ABSTRACT

Background

Aspirin and heparin are widely used as preventive strategy to reduce the high risk of recurrent pregnancy loss in women with antiphospholipid antibodies (aPL).

This review supersedes a previous, out-of-date review that evaluated all potential therapies for preventing recurrent pregnancy loss in women with aPL. The current review focusses on a narrower scope because current clinical practice is restricted to using aspirin or heparins, or both for women with aPL in an attempt to reduce pregnancy complications.

Objectives

To assess the effects of aspirin or heparin, or both for improving pregnancy outcomes in women with persistent (on two separate occasions) aPL, either lupus anticoagulant (LAC), anticardiolipin (aCL) or a β_2 -glycoprotein-I antibodies (a β_2 GPI) or a combination, and recurrent pregnancy loss (two or more, which do not have to be consecutive).

Search methods

We searched Cochrane Pregnancy and Childbirth's Trials Register, [ClinicalTrials.gov](https://www.clinicaltrials.gov), the WHO International Clinical Trials Registry Platform (ICTRP) (3 June 2019), and reference lists of retrieved studies. Where necessary, we attempted to contact trial authors.

Selection criteria

Randomised, cluster-randomised and quasi-randomised controlled trials that assess the effects of aspirin, heparin (either low-molecular-weight heparin (LMWH) or unfractionated heparin (UFH)), or a combination of aspirin and heparin compared with no treatment, placebo or another, on pregnancy outcomes in women with persistent aPL and recurrent pregnancy loss were eligible. All treatment regimens were considered.

Data collection and analysis

Two review authors independently assessed trials for inclusion criteria and risk of bias. Two review authors independently extracted data and checked them for accuracy and the certainty of the evidence was assessed using the GRADE approach.

Main results

Eleven studies (1672 women) met the inclusion criteria; nine randomised controlled trials and two quasi-RCTs. The studies were conducted in the USA, Canada, UK, China, New Zealand, Iraq and Egypt. One included trial involved 1015 women, all other included trials had considerably lower numbers of participants (i.e. 141 women or fewer).

Some studies had high risk of selection and attrition bias, and many did not include sufficient information to judge the risk of reporting bias. Overall, the certainty of evidence is low to very low due to the small numbers of women in the studies and to the risk of bias.

The dose and type of heparin and aspirin varied among studies. One study compared aspirin alone with placebo; no studies compared heparin alone with placebo and there were no trials that had a no treatment comparator arm during pregnancy; five studies explored the efficacy of heparin (either UFH or LMWH) combined with aspirin compared with aspirin alone; one trial compared LMWH with aspirin; two trials compared the combination of LMWH plus aspirin with the combination of UFH plus aspirin; two studies evaluated the combination of different doses of heparin combined with aspirin. All trials used aspirin at a low dose.

Aspirin versus placebo

We are very uncertain if aspirin has any effect on live birth compared to placebo (risk ratio (RR) 0.94, 95% confidence interval (CI) 0.71 to 1.25, 1 trial, 40 women, very low-certainty evidence).

We are very uncertain if aspirin has any effect on the risk of pre-eclampsia, pregnancy loss, preterm delivery of a live infant, intrauterine growth restriction or adverse events in the child, compared to placebo. We are very uncertain if aspirin has any effect on adverse events (bleeding) in the mother compared with placebo (RR 1.29, 95% CI 0.60 to 2.77, 1 study, 40 women). The certainty of evidence for these outcomes is very low because of imprecision, due to the low numbers of women involved and the wide 95% CIs, and also because of risk of bias.

Venous thromboembolism and arterial thromboembolism were not reported in the included studies.

Heparin plus aspirin versus aspirin alone

Heparin plus aspirin may increase the number of live births (RR 1.27, 95% CI 1.09 to 1.49, 5 studies, 1295 women, low-certainty evidence).

We are uncertain if heparin plus aspirin has any effect on the risk of pre-eclampsia, preterm delivery of a live infant, or intrauterine growth restriction, compared with aspirin alone because of risk of bias and imprecision due to the low numbers of women involved and the wide 95% CIs. We are very uncertain if heparin plus aspirin has any effect on adverse events (bleeding) in the mother compared with aspirin alone (RR 1.65, 95% CI 0.19 to 14.03, 1 study, 31 women).

No women in either the heparin plus aspirin group or the aspirin alone group had heparin-induced thrombocytopenia, allergic reactions, or venous or arterial thromboembolism. Similarly, no infants had congenital malformations.

Heparin plus aspirin may reduce the risk of pregnancy loss (RR 0.48, 95% CI 0.32 to 0.71, 5 studies, 1295 women, low-certainty evidence).

When comparing LMWH plus aspirin versus aspirin alone the pooled RR for live birth was 1.20 (95% CI 1.04 to 1.38, 3 trials, 1155 women). In the comparison of UFH plus aspirin versus aspirin alone, the RR for live birth was 1.74 (95% CI 1.28 to 2.35, 2 trials, 140 women).

Authors' conclusions

The combination of heparin (UFH or LMWH) plus aspirin during the course of pregnancy may increase live birth rate in women with persistent aPL when compared with aspirin treatment alone. The observed beneficial effect of heparin was driven by one large study in which LMWH plus aspirin was compared with aspirin alone. Adverse events were frequently not, or not uniformly, reported in the included studies. More research is needed in this area in order to further evaluate potential risks and benefits of this treatment strategy, especially among women with aPL and recurrent pregnancy loss, to gain consensus on the ideal prevention for recurrent pregnancy loss, based on a risk profile.

PLAIN LANGUAGE SUMMARY

Anticoagulant drugs for the prevention of recurrent miscarriage in women with antiphospholipid antibodies

We set out to determine if antithrombotic drugs improve pregnancy outcomes for women with persistent antiphospholipid antibody levels who have had a number of miscarriages.

What is the issue?

Phospholipid molecules help form the cell membranes and are critical to a cell's ability to function. The immune system can develop antibodies that are directed against proteins attached to the phospholipids. Different types of antiphospholipid antibodies exist. Presence of these antibodies can lead to the development of blood clots in either veins or arteries, but also repeated pregnancy losses.

Why is this important?

Antiphospholipid antibodies are associated with a higher risk of pregnancy complications, including the risk of pregnancy loss. Use of antithrombotic drugs during pregnancy may help prevent pregnancy loss for women who have had recurrent miscarriages. Aspirin is an anti-inflammatory drug that reduces platelet aggregation and blood clotting. Heparin is a potent anticoagulant that prevents blood clot formation. Aspirin and heparin may reduce the risk of miscarriage associated with antiphospholipid antibodies. Low-molecular-weight heparin is easier to use and causes less side effects for the mother than undivided or unfractionated heparin.

What evidence did we find?

We searched the medical literature for evidence from randomised controlled trials up to June 2019. We identified 11 studies involving 1672 women who had previously experienced at least two pregnancy losses and had persistent antiphospholipid antibodies in their blood. Most studies started eligible women on aspirin before conception with women randomly assigned to receive additional heparin, or not, once pregnancy was confirmed. The dose and type of heparin varied among studies, as did timing for when treatment was started and the length of time women were treated.

The evidence we identified is low certainty due to the small numbers of women in the studies and to the risk of bias in the studies.

Compared to placebo, we are very uncertain if aspirin has any effect on live birth, pre-eclampsia, pregnancy loss, preterm delivery of a live infant, intrauterine growth restriction or adverse events in the child or in the mother. Venous thromboembolism and arterial thromboembolism were not reported in the studies investigating aspirin compared with placebo.

Heparin plus aspirin may increase the number of live births and may reduce the risk of pregnancy loss.

Compared with aspirin alone, we are uncertain if heparin plus aspirin has any effect on the risk of pre-eclampsia, preterm delivery of a live infant, intrauterine growth restriction, or bleeding in the mother.

No women in either the heparin plus aspirin group or the aspirin alone group had heparin-induced thrombocytopenia, allergic reactions, or venous or arterial thromboembolism. Similarly, no infants had congenital malformations.

What does this mean?

The combination of heparin with aspirin during the course of pregnancy for women with persistent antiphospholipid antibodies may lead to a higher number of live births than treatment with aspirin alone. We are uncertain about the safety of heparin and aspirin for mothers and infants because of the lack of reporting of adverse events. Future trials should recruit adequate numbers of women and to fully evaluate the risks and benefits of this treatment strategy.

SUMMARY OF FINDINGS

Summary of findings 1. Aspirin compared to placebo for improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss

Aspirin compared to placebo for improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss

Patient or population: improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss

Setting:

Intervention: aspirin

Comparison: placebo

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	N° of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with placebo	Risk with Aspirin				
Live birth	Study population		RR 0.94 (0.71 to 1.25)	40 (1 RCT)	⊕⊕⊕⊕ VERY LOW ^{1 2}	
	850 per 1,000	799 per 1,000 (603 to 1,000)

	350 per 1,000	451 per 1,000 (210 to 969)				
Venous thromboembolism	Not reported					
Arterial thromboembolism	Not reported					
Pregnancy loss	Study population		RR 1.33 (0.34 to 5.21)	40 (1 RCT)	⊕⊕⊕⊕ VERY LOW ^{1 2}	
	150 per 1,000	200 per 1,000 (51 to 782)				
Preterm delivery of a live infant	2/16 in the aspirin group and 0/17 in the placebo group had a preterm delivery of a live infant		RR 5.29 (0.27 to 102.49)	33 (1 RCT)	⊕⊕⊕⊕ VERY LOW ^{1 2}	

Intrauterine growth restriction	Study population	RR 0.27 (0.03 to 2.13)	33 (1 RCT)	⊕⊕⊕⊕ VERY LOW ^{1 2}
	235 per 1,000 64 per 1,000 (7 to 501)			
Adverse events in the child - Congenital malformations	Study population	RR 1.06 (0.07 to 15.60)	33 (1 RCT)	⊕⊕⊕⊕ VERY LOW ^{1 2}
	59 per 1,000 62 per 1,000 (4 to 918)			

***The risk in the intervention group** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RCT:** randomised controlled trial; **RR:** Risk ratio

GRADE Working Group grades of evidence

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect.

¹ Downgraded one level due to serious risk of selection and attrition bias

² Downgraded two levels due to very serious imprecision: few participants and wide confidence intervals crossing the line of no effect

Summary of findings 2. Heparin plus aspirin compared to aspirin for improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss

Heparin plus aspirin compared to aspirin for improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss

Patient or population: women with persistent antiphospholipid antibodies and recurrent pregnancy loss

Setting: mix of multicentre and single-centre trials, based in the UK, the USA, Canada and China

Intervention: heparin (UFH or LMWH) and aspirin

Comparison: aspirin

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	Nº of participants (studies)	Certainty of the evidence (GRADE)	Comments

- 6 Downgraded two levels due to very serious imprecision: few participants and wide confidence interval crossing the line of not effect

BACKGROUND

Description of the condition

Antiphospholipid antibodies (aPL) are directed against phospholipids and include lupus anticoagulant (LAC), immunoglobulin G (IgG) or immunoglobulin M (IgM) anticardiolipin (aCL) and IgG or IgM anti- β_2 -glycoprotein-I (β_2 GPI) antibodies. The presence of aPL is associated with a hypercoagulable state (Harris 1983), which is an abnormally increased tendency toward clotting of the blood. aPL are predominantly known for their role in antiphospholipid syndrome (APS), also known as antiphospholipid antibody syndrome or Hughes syndrome. APS is an autoimmune disorder characterised by the occurrence of a clinical event (recurrent pregnancy loss and/or thrombosis) in the persistent presence of aPL. Currently, the diagnosis of APS is made according to the Sydney criteria established in 2006 (also known as the revised Sapporo criteria), and is based on both clinical and biochemical findings (Miyakis 2006). The clinical criteria include venous and/or arterial thrombosis and well-defined pregnancy complications such as (recurrent) pregnancy loss (miscarriage or fetal loss) and pre-eclampsia, whereas the biochemical criteria include persistent (after a 12-week window) presence of aPL. The diagnosis of APS is made if a woman meets at least one of the clinical criteria and at least one of the biochemical criteria.

Antiphospholipid antibodies are reported to be present in 1% to 5.6% of healthy individuals, with prevalence increasing with age (Durcan 2016). In women with recurrent first trimester pregnancy losses, the presence of these antibodies has been detected in 15% (Rai 1995). Presence of antibodies without clinical events does not indicate treatment, as only a minority of individuals with aPL will develop APS (Ruiz-Irastorza 2010). The prevalence of APS is estimated to range from 40 to 50 per 100,000 individuals, and is especially increased in women with autoimmune and rheumatic diseases, such as systemic lupus erythematosus (SLE) (Gómez-Puerta 2014; Love 1990).

Knowledge on the mechanisms and triggers inducing the development and persistence of aPL and the different clinical manifestations are poorly understood. It is thought that beside the presence of the antibodies, a trigger such as pregnancy, hormonal therapy, malignancy, smoking or infection, plays a key role in disease initiation (Meroni 2018). As for APS, knowledge and understanding of the disorder evolve constantly, but uncertainty regarding pathogenesis, diagnosis, as well as optimal treatment remains (Schreiber 2018).

Recently it has been suggested that women with different disease manifestations may represent different subgroups with subsequently, a different course of disease in terms of recurrence risk and type of events. For example, women presenting with thrombotic events may represent a different subgroup from women presenting with pregnancy complications, or women presenting with venous events might be a different subgroup again from women presenting with arterial events (Meroni 2012; Lockshin 2013). Moreover, it has been suggested that the risk of (recurrent) pregnancy complications may differ between groups of women. For example, the risk of pregnancy complications (and type of complication) may differ in women with previous complications compared with women with no previous complication, women with high and low aPL titres, and women with positive versus negative LAC antibodies (Erkan 2002; Ioannou 2010; Lockshin 2012).

Description of the intervention

Aspirin and heparins, either unfractionated heparin (UFH) or low-molecular-weight heparin (LMWH), are antithrombotic drugs, often prescribed with the intention to prevent excessive clotting of the blood. Aspirin, also known as acetylsalicylic acid, prevents the formation of thromboxane A₂, and inhibits platelet aggregation (Vane 1971; Vane 2003). Heparins inhibit thrombus formation by binding to the natural anticoagulant antithrombin, which results in a potent activation of this enzyme (Chaung 2001). The preferred route of UFH administration is either by a continuous intravenous administration or by subcutaneous injection, whereas LMWH is administered by subcutaneous injection. Important side effects of heparin therapy include haemorrhage, heparin-induced thrombocytopenia and osteoporosis. Heparins do not cross the placenta and are considered safe for the fetus. Treatment with therapeutic doses of UFH requires frequent monitoring, which LMWH treatment does not. For several indications, when studied in the non-pregnant population, LMWH was found to have similar efficacy and a superior safety profile (Green 1994; Nurmohamed 1992). The antithrombotic effects in pregnant women may not be alike, due to differences in protein binding. Inconsistent findings have been reported and a direct comparison in a large clinical trial has not yet been made (Ensom 2004; Pariente 2016).

How the intervention might work

Antithrombotic therapy has been found to reduce the risk of recurrent (either venous or arterial) thrombosis in APS (ACOG 2012). Traditionally it is hypothesised that pregnancy complications in APS are also the result of a hypercoagulable state, partially by thrombosis of the placental vasculature. Recent hypotheses describe a more intertwined pathophysiological mechanism in which both the coagulation system, as well as inflammation are involved (Meroni 2018; Redecha 2008; Samarkos 2012). Aspirin and heparin may both have a beneficial effect on coagulation and inflammation (Kozłowski 2011; Vane 2003; Vignoli 2006), and are thought to reduce the risk of pregnancy loss in APS. Antiphospholipid antibodies directly inhibit trophoblast proliferation and differentiation, which can lead to defective placentation (Meroni 2018). This inhibitory effect of aPL on proliferation of trophoblasts has been proposed as the pathogenic mechanism in early pregnancy loss, whereas late obstetrical complications have been attributed to a dysfunctional placenta (Burton 2009; Di Simone 2000; Derksen 2008). The effects of UFH on trophoblast proliferation have not been evaluated, but LMWH has the capacity to stimulate proliferation and protect against apoptosis (cell death) of trophoblasts (Shomer 2016). For this reason, if LMWH administration had a beneficial effect in prevention of early miscarriage, the effects would be observed early during pregnancy. Moreover, it has been suggested that aPLs affect the production of several chemokines and angiogenic factors by human endometrial endothelial cells, which may contribute to impaired placentation and vascular transformation. Noticeably, one recent study demonstrated that LMWH and aspirin, alone or in combination, exacerbated the changes in human endometrial endothelial function mediated by aPL, rather than protecting against them (Quao 2018).

Why it is important to do this review

This is a new review which will supersede the previous, out-of-date review by Empson and colleagues (Empson 2005), which

included all potential therapies for preventing recurrent pregnancy loss in women with aPL. This new review has a narrower scope than [Empson 2005](#), as currently in clinical practice only aspirin or heparins, or both are used in women with aPL in an attempt to reduce pregnancy complications. However, it is uncertain whether these antithrombotic therapies improve pregnancy outcome and reduce the risk of pregnancy complications in women with persistent (on two occasions) aPL.

OBJECTIVES

To assess the effects of aspirin or heparin, or both for improving pregnancy outcomes in women with persistent (on two separate occasions) antiphospholipid antibodies (aPL), either lupus anticoagulant (LAC), anticardiolipin (aCL) or $\alpha\beta_2$ -glycoprotein-I antibodies ($\alpha\beta_2$ GPI), or a combination, and recurrent pregnancy loss (two or more, which do not have to be consecutive).

METHODS

Criteria for considering studies for this review

Types of studies

All randomised controlled trials (RCTs), cluster-randomised trials and quasi-randomised controlled trials evaluating aspirin or heparin, or both for improving pregnancy outcome in women with recurrent pregnancy loss and persistent antiphospholipid antibodies (aPL). Cross-over trials were excluded due to the nature of outcomes considered. Studies published in abstract form only were included if sufficient data were available to determine eligibility.

Types of participants

This review includes women with recurrent (two or more, which do not have to be consecutive) pregnancy loss in the presence of persistent (on two separate occasions) aPL. Pregnancy loss entailed any miscarriage or fetal loss, however defined by the trial authors. aPL presence was determined by either positive LAC, aCL or $\alpha\beta_2$ antibodies, or a combination.

Types of interventions

Any comparison of aspirin, heparin (either low-molecular-weight heparin (LMWH) or unfractionated heparin (UFH)) or a combination of aspirin and heparin with no treatment, placebo or another was included. Any treatment regimen was considered.

Types of outcome measures

Primary outcomes

1. Live birth

Secondary outcomes

For the mother

1. Pre-eclampsia (definition according to original study)
2. Adverse events in the mother (definitions according to original study: (A) bleeding, (B) heparin-induced thrombocytopenia, (C) allergic reactions)
3. Venous thromboembolism
4. Arterial thromboembolism
5. Pregnancy loss

For the child

1. Preterm delivery of a live infant (before 37 weeks, 24 to 28 weeks, 28 to 32 weeks and 32 to 37 weeks)
2. Intrauterine growth restriction (definition according to original study)
3. Adverse events in the child (definitions according to original study: (A) congenital malformations, (B) neonatal bleeding)

Search methods for identification of studies

The following search methods section was based on a standard template used by Cochrane Pregnancy and Childbirth.

Electronic searches

We searched Cochrane Pregnancy and Childbirth's Trials Register by contacting their Information Specialist (3 June 2019).

The Register is a database containing over 25,000 reports of controlled trials in the field of pregnancy and childbirth. It represents over 30 years of searching. For full current search methods used to populate Pregnancy and Childbirth's Trials Register including the detailed search strategies for CENTRAL, MEDLINE, Embase and CINAHL; the list of handsearched journals and conference proceedings, and the list of journals reviewed via the current awareness service, please follow this [link](#).

Briefly, Cochrane Pregnancy and Childbirth's Trials Register is maintained by their Information Specialist and contains trials identified from:

1. monthly searches of the Cochrane Central Register of Controlled Trials (CENTRAL);
2. weekly searches of MEDLINE (Ovid);
3. weekly searches of Embase (Ovid);
4. monthly searches of CINAHL (EBSCO);
5. handsearches of 30 journals and the proceedings of major conferences;
6. weekly current awareness alerts for a further 44 journals plus monthly BioMed Central email alerts.

Search results are screened by two people and the full text of all relevant trial reports identified through the searching activities described above is reviewed. Based on the intervention described, each trial report is assigned a number that corresponds to a specific Pregnancy and Childbirth review topic (or topics), and is then added to the Register. The Information Specialist searches the Register for each review using this topic number rather than keywords. This results in a more specific search set that has been fully accounted for in the relevant review sections ([Included studies](#); [Excluded studies](#); [Ongoing studies](#)).

In addition, we searched [ClinicalTrials.gov](#) and the WHO International Clinical Trials Registry Platform (ICTRP) (3 June 2019) for unpublished, planned and ongoing trial reports using the search methods detailed in [Appendix 1](#).

Searching other resources

We handsearched the reference lists of retrieved studies and relevant review articles. We did not apply any language or date restrictions.

Data collection and analysis

The following methods section was based on a standard template used by Cochrane Pregnancy and Childbirth.

Selection of studies

Two review authors independently assessed for inclusion all potential studies identified as a result of the search strategy. All disagreements were resolved through discussion and if necessary a third author was involved to have the final vote.

We created a study flow diagram to map out the number of records identified, included and excluded (Moher 2009).

Data extraction and management

We designed a form to extract data. Two review authors independently extracted data for every eligible study using the agreed form. A consensus meeting was held to deal with differences in the extracted data, and if necessary a third review author was involved to have the final vote.

All extracted data were entered into the Review Manager 5 (RevMan 5) software (RevMan 2014) and checked for accuracy. In case of uncertainties regarding the study data, we contacted authors of the specific study for additional information.

Assessment of risk of bias in included studies

Two review authors independently assessed risk of bias for each study using the criteria outlined in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2017). Any disagreement was resolved by discussion or by involving a third assessor.

(1) Random sequence generation (checking for possible selection bias)

We described for each included study the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.

We assessed the method as:

- low risk of bias (any truly random process, e.g. random number table; computer random-number generator);
- high risk of bias (any non-random process, e.g. odd or even date of birth; hospital or clinic record number);
- unclear risk of bias.

(2) Allocation concealment (checking for possible selection bias)

We described for each included study the method used to conceal allocation to interventions prior to assignment and assessed whether intervention allocation could have been foreseen in advance of, or during recruitment, or changed after assignment.

We assessed the methods as:

- low risk of bias (e.g. telephone or central randomisation; consecutively-numbered, sealed, opaque envelopes);
- high risk of bias (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth);
- unclear risk of bias.

(3.1) Blinding of participants and personnel (checking for possible performance bias)

We described for each included study the methods used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. We considered that studies were at low risk of bias if they were blinded, or if we judged that the lack of blinding was unlikely to affect results. We assessed risk of bias by blinding separately for different outcomes or classes of outcomes.

We assessed the methods as:

- low, high or unclear risk of bias for participants;
- low, high or unclear risk of bias for personnel.

(3.2) Blinding of outcome assessment (checking for possible detection bias)

We described for each included study the methods used, if any, to blind outcome assessors from knowledge of which intervention a participant received. We assessed blinding separately for different outcomes or classes of outcomes.

We assessed methods used to blind outcome assessment as:

- low, high or unclear risk of bias.

(4) Incomplete outcome data (checking for possible attrition bias due to the amount, nature and handling of incomplete outcome data)

We described for each included study, and for each outcome or class of outcomes, the completeness of data including attrition and exclusions from the analysis. We stated whether attrition and exclusions were reported and the numbers included in the analysis at each stage (compared with the total randomised participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. Where sufficient information was reported, or could be supplied by the trial authors, we planned to re-include missing data in the analyses that we undertook.

We assessed the methods as:

- low risk of bias (e.g. no missing outcome data; missing outcome data balanced across groups);
- high risk of bias (e.g. numbers or reasons for missing data imbalanced across groups; 'as-treated' analysis done with substantial departure of intervention received from that assigned at randomisation);
- unclear risk of bias.

(5) Selective reporting (checking for reporting bias)

We described for each included study how we investigated the possibility of selective outcome reporting bias and what we found.

We assessed the methods as:

- low risk of bias (where it is clear that all of the study's pre-specified outcomes and all expected outcomes of interest to the review have been reported);
- high risk of bias (where not all the study's pre-specified outcomes have been reported; one or more reported primary

outcomes were not pre-specified; outcomes of interest have been reported incompletely and so cannot be used; study failed to include results of a key outcome that would have been expected to have been reported);

- unclear risk of bias.

(6) Other bias (checking for bias due to problems not covered by (1) to (5) above)

We described for each included study any important concerns we had about other possible sources of bias.

We assessed whether each study was free of other problems that could put it at risk of bias:

- low risk of other bias;
- high risk of other bias;
- unclear whether there is risk of other bias.

(7) Overall risk of bias

We made explicit judgements about whether studies are at high risk of bias, according to the criteria given in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2017). With reference to (1) to (6) above, we planned to assess the likely magnitude and direction of the bias and whether we considered it is likely to impact on the findings. We explored the impact of the level of bias through undertaking sensitivity analyses - see [Sensitivity analysis](#).

Measures of treatment effect

Dichotomous data

For dichotomous data, we presented results as summary risk ratio with 95% confidence intervals.

Continuous data

We did not include any continuous outcome data in the current review. In future updates, we will use the mean difference if outcomes are measured in the same way between trials. We will use the standardised mean difference to combine trials that measure the same outcome, but used different methods.

Unit of analysis issues

Cluster-randomised trials

There were no cluster-randomised trials identified to date for inclusion; we will however include them in future updates in the analyses along with individually-randomised trials. We will adjust for sample sizes, guided by the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2017). If possible, we will use the estimate of the intra-cluster correlation coefficient (ICC) derived from the study, from a similar study or from a study with a similar population. When we use ICCs from external sources, we will mention it explicitly in the review, and we will conduct appropriate sensitivity analyses. When both cluster-randomised trials and individually-randomised trials are encountered, we will use relevant data for the review. We will combine results from both cluster-randomised trials and individually-randomised trials if little heterogeneity is observed between study designs, provided that the interaction between the effect of intervention and choice of randomisation unit is considered to be unlikely. Heterogeneity will be acknowledged in the randomisation unit and we will conduct a sensitivity analysis to explore the effects of this randomisation unit.

Multiple-arm studies

There were no multi-arm trials identified to date for inclusion. For future updates, all intervention arms will be reported and described in the [Characteristics of included studies](#) table, including the number of women randomised to each arm. We will combine groups, to create a single pair-wise comparison if possible. Appropriate pair-wise comparisons will then be selected for the meta-analysis, in order to avoid double-counting of one of the arms. We will declare in the [Characteristics of included studies](#) table if a trial has an intervention arm that is not applicable or relevant to our review question. We will only include the intervention and control groups that meet the eligibility criteria in the analyses.

Cross-over trials

We considered cross-over trials an inappropriate design for this intervention.

Dealing with missing data

For every individual included study, we determined the level of attrition. We evaluated the impact on the overall assessment of the intervention of including studies with high proportions of missing data by conducting a sensitivity analysis without these studies.

For all outcomes, analyses were carried out, as far as possible, on an intention-to-treat basis; we attempted to include all participants randomised in the analyses, and analysed these participants according to their allocated treatment assignment, regardless of whether the allocated intervention was received. For each outcome in every trial, the denominator was the number of randomised participants minus the participants whose outcomes are missing. In studies with more than 5% loss to follow-up, we planned to perform a best-case scenario analysis (losses to follow-up assumed to have a positive outcome, e.g. primary outcome) and a worst-case scenario analysis (losses to follow-up assumed to have a negative outcome, e.g. no primary outcome) - we did not need to perform best case/worst case analyses because the primary outcome was available for all women.

Assessment of heterogeneity

In all meta-analyses we assessed statistical heterogeneity using the Tau^2 , I^2 (Higgins 2003) and Chi^2 statistics (Deeks 2011). We regarded heterogeneity as substantial if Tau^2 was greater than zero and either the I^2 statistic was greater than 30%, or there was a P value equal to or less than 0.10 in the Chi^2 test for heterogeneity.

Assessment of reporting biases

None of the meta-analyses in the current review concerned 10 or more studies. If in future updates, if the meta-analysis includes 10 or more studies, we will explore potential reporting bias (mainly publication bias) using funnel plots and visually assess them. We will prepare funnel plots and visually assess them for asymmetry. If visual assessment leads us to suspect asymmetry, we will conduct additional analyses to explore these potential biases.

Data synthesis

We carried out statistical analysis using RevMan 5 software (RevMan 2014). We used fixed-effect meta-analysis for combining data where it was reasonable to assume that studies were estimating the same underlying treatment effect: that is, where trials were examining the same intervention, and the trials' populations and

methods were judged sufficiently similar. Where there was clinical heterogeneity sufficient to expect that the underlying treatment effects differed between trials, or if we detected substantial statistical heterogeneity, we used random-effects meta-analysis to produce an overall summary, if an average treatment effect across trials was considered clinically meaningful. We treated the random-effects summary as the average of the range of possible treatment effects and we discussed the clinical implications of treatment effects differing between trials. If the average treatment effect was not clinically meaningful, we did not combine trials.

Where we used random-effects analyses, we presented the results as the average treatment effect with 95% confidence intervals, and the estimates of Tau² and I² statistic.

Subgroup analysis and investigation of heterogeneity

For the comparison 'heparin with or without aspirin versus aspirin alone', we did subgroup analysis per type of heparin, as follows:

1. UFH plus aspirin versus aspirin alone
2. LMWH plus aspirin versus aspirin alone

Over the last two decades or so, clinical practice with regard to heparin treatment has changed from using UFH subcutaneously to the current standard of care of LMWH. For this reason, we consider reporting the subgroup results for both UFH and LMWH to be a more detailed description of the evidence and highly relevant for current clinical practice.

Where we identified substantial heterogeneity, we planned to investigate it using subgroup analyses and sensitivity analyses. We planned to consider whether an overall summary was meaningful, and if it was, used random-effects analysis to produce it.

The risk of (recurrent) pregnancy complications may differ between different subgroups of women, such as previous placenta-mediated complications, number of pregnancy losses, high- or low-titre antibodies and positive or negative lupus anticoagulant (LAC) antibodies. For this reason, the following subgroup analyses were pre-specified.

1. Previous placenta-mediated complication (pre-eclampsia; intrauterine growth restriction or placental abruption, or both) versus no previous placenta-mediated complication
2. Two versus three or more pregnancy losses (which do not have to be consecutive)
3. High-titre antibodies versus low-titre antibodies
4. Positive lupus anticoagulant (LAC) antibodies versus negative LAC antibodies

We planned to use the primary outcome (live birth) in subgroup analyses.

We planned to assess subgroup differences by interaction tests available within RevMan 5 (RevMan 2014). We planned to report the results of subgroup analyses quoting the Chi² statistic and P value, and the interaction test I² statistic value.

Sensitivity analysis

Where possible, we carried out sensitivity analyses to explore the effect of use of the full Sapporo criteria for APS, with studies not using the full criteria excluded from the analyses; and trial quality

(including quasi-randomised trials), assessed by random sequence generation and concealment of allocation, with studies assessed as high risk of bias on these domains being excluded from the analyses. Sensitivity analyses were limited to the primary outcome.

In future updates, where cluster-randomised trials are included, we plan to carry out sensitivity analyses to explore the effects of variation in intra-cluster correlation coefficient (ICC) values and in the randomisation unit (i.e. individual versus cluster trials).

Summary of findings and assessment of the certainty of the evidence

The certainty of evidence was assessed using the GRADE approach as outlined in the [GRADE handbook](#) in order to assess the certainty of the body of evidence relating to the following outcomes for the two main comparisons.

1. Aspirin versus placebo
2. Heparin plus aspirin versus aspirin alone

Primary outcomes

1. Live birth

Secondary outcomes

For the mother

1. Pre-eclampsia (definition according to original study)
2. Adverse events in the mother (definitions according to original study: (A) bleeding, (B) heparin-induced thrombocytopenia, (C) allergic reactions)
3. Venous thromboembolism
4. Arterial thromboembolism
5. Pregnancy loss

For the child

1. Preterm delivery of a live infant (before 37 weeks, 24 to 28 weeks, 28 to 32 weeks and 32 to 37 weeks)
2. Intrauterine growth restriction (definition according to original study)
3. Adverse events in the child (definitions according to original study: (A) congenital malformations, (B) neonatal bleeding)

We used the [GRADEpro](#) Guideline Development Tool to import data from RevMan 5 (RevMan 2014) in order to create 'Summary of findings' tables for comparison 1 (aspirin versus placebo) and comparison 2 (heparin plus aspirin versus aspirin alone). A summary of the intervention effect and a measure of certainty for each of the above outcomes in these comparisons was produced using the GRADE approach. The GRADE approach uses five considerations (study limitations, consistency of effect, imprecision, indirectness and publication bias) to assess the certainty of the body of evidence for each outcome. The evidence can be downgraded from 'high certainty' by one level for serious (or by two levels for very serious) limitations, depending on assessments for risk of bias, indirectness of evidence, serious inconsistency, imprecision of effect estimates or potential publication bias.

RESULTS**Description of studies**

See: [Characteristics of included studies](#); [Characteristics of excluded studies](#).

Results of the search

See: [Figure 1](#)

Figure 1. Study flow diagram.

As of June 2019, the search strategy identified 127 records through database screening. The title and abstract screening identified 91 potentially eligible citations. The full-text screening of these 91 citations identified 11 eligible randomised controlled trials

published as full reports (Alalaf 2012; Bao 2017; Farquharson 2002; Fouda 2010; Fouda 2011; Kutteh 1996a; Kutteh 1996b; Laskin 2009; Pattison 2000; Rai 1997; Stephenson 2004). We identified two registered, but unpublished trials (Abdelhafez 2014; Rodger 2017). We did not identify any cluster-randomised trials that met our inclusion criteria. None of the studies only published as abstracts were included, as insufficient data were available to determine eligibility.

Included studies

A total of 1672 women were enrolled in the 11 included trials; nine were randomised controlled trials and two were quasi-randomised controlled trials (Kutteh 1996a; Kutteh 1996b). The study designs, inclusion and exclusion criteria and interventions are shown in the [Characteristics of included studies](#) tables. The studies were conducted in the USA, Canada, the UK, China, New Zealand, Iraq and Egypt. One included trial involved 1015 women (Bao 2017), all other included trials had considerably lower numbers of participants (i.e. 141 women or fewer).

One study compared aspirin with placebo (n = 40) (Pattison 2000). No study compared heparin alone with placebo and we did not identify trials with a no treatment comparator arm during pregnancy. Five studies explored the efficacy of heparin plus aspirin with aspirin alone; two studies evaluated the combination of unfractionated heparin (UFH) plus aspirin in comparison with aspirin alone (n = 140) (Kutteh 1996a; Rai 1997), three studies used low-molecular weight heparin (LMWH) plus aspirin and compared this to aspirin alone (n = 1155) (Bao 2017; Farquharson 2002; Laskin 2009). One trial compared LMWH with aspirin (n = 141) (Alalaf 2012). Two trials compared LMWH with UFH, both combined with aspirin (n = 86) (Fouda 2011; Stephenson 2004). Two studies investigated the combination of different doses of heparin plus aspirin; one compared high-dose UFH with low-dose UFH, both combined with aspirin (n = 50) (Kutteh 1996b), whereas the other study compared high-dose LMWH with low-dose LMWH, both combined with aspirin (n = 60) (Fouda 2010).

Characteristics of participants

The characteristics of the trial participants are summarised in [Table 1](#), though these were not completely reported in all studies. One trial also included participants who did not have antiphospholipid antibodies (aPL) (Laskin 2009) and we included only data from the subgroup of participants with aPL from this study (n = 42/88) (Laskin 2009); we contacted the authors to provide data on the secondary outcomes for the subgroup of aPL-positive participants, but we did not receive a reply.

Prior pregnancy losses

The mean number of previous pregnancy losses in the studies ranged from 3 to 4.3 (Alalaf 2012; Farquharson 2002; Fouda 2010; Fouda 2011; Kutteh 1996a; Kutteh 1996b; Rai 1997; Stephenson 2004). In eight trials, participants met the clinical criteria for antiphospholipid syndrome (APS) with three or more early miscarriages. Three trials included women with two or more consecutive pregnancy losses (Alalaf 2012; Bao 2017; Laskin 2009). Previous pregnancy losses concerned mostly early pregnancy losses, but less than half of the included studies specified this (Kutteh 1996a; Kutteh 1996b; Laskin 2009; Pattison 2000; Rai 1997). Full details on pregnancy losses are provided in the characteristics of included studies ([Included studies](#)).

Presence of antiphospholipid antibodies (aPL)

All trials included participants with persistent presence of aPL, but the time-frame between tests differed per study. Two trials included patients with aPL tested at least six weeks apart (Farquharson 2002; Stephenson 2004); three trials with tests at least eight weeks apart (Alalaf 2012; Laskin 2009; Rai 1997); three trials with tests at least 12 weeks apart (Bao 2017; Fouda 2010; Fouda 2011); and three trials did not mention the time-frame (Kutteh 1996a; Kutteh 1996b; Pattison 2000). None of the included trials reported women with a β_2 -GPI antibodies. [Table 1](#) lists the aPL-profiles for trial participants.

Dose and type of aspirin and heparin

Low-dose aspirin was used in all trials. In six trials a dose of aspirin of 75 mg/day was used (Bao 2017; Farquharson 2002; Fouda 2010; Fouda 2011; Pattison 2000; Rai 1997), in four trials the dose was 81 mg/day (Kutteh 1996a; Kutteh 1996b; Laskin 2009; Stephenson 2004), and in one trial the dose used was 100 mg/day (Alalaf 2012). The types of LMWH included bemiparin in a dose of 2500 IU/day (Alalaf 2012), enoxaparin in a dose of 20 mg or 40 mg per day (Fouda 2010; Fouda 2011), dalteparin in a dose of 5000 IU/day (Laskin 2009) or 2500 IU/day (Stephenson 2004), nadroparin in a dose of 4100 IU/day (Bao 2017), and in one trial the type of LMWH was not mentioned, but administered in a dose of 5000 IU/day (Farquharson 2002). The dose of UFH was 5000 IU twice daily in both the trial of Kutteh 1996a and the trial of Stephenson 2004, with the latter with increasing the dose of administered heparin (LMWH or UFH) during the trial. One trial compared a lower and a higher dose of UFH (Kutteh 1996b); in the high-dose UFH group, the doses of heparin were adjusted to maintain 1.2 to 1.5 times the baseline partial thromboplastin time (PTT) and were increased by 1000 U/dose weekly until the desired range was achieved, whereas in the low-dose UFH group the dose of heparin was adjusted to maintain the PTT at the upper limits of the normal range in the reference laboratory.

Initiation and duration of treatment

There was a wide variation in treatment initiation and duration between trials. One trial randomised women to aspirin, which was started preconceptionally and continued upon pregnancy confirmation or to LMWH commencing at the confirmation of pregnancy, continuing either treatment until 36 weeks of gestation (Alalaf 2012). In one trial, participants were randomised before 12 weeks of gestation, with a mean gestation age of 6.7 weeks at randomisation, and received treatment until delivery (Farquharson 2002). In two trials, aspirin was started preconceptionally up to 36 gestational weeks, with a heparin (LMWH or UFH) started when the serum pregnancy test became positive until delivery, when it was switched to twice-daily UFH (Fouda 2010; Fouda 2011). Two trials initiated aspirin preconceptionally in all participants and at the first confirmed pregnancy test, patients were instructed to continue aspirin alone or to add subcutaneous injections of heparin twice-daily (Kutteh 1996a), or all participants were started on heparin injections (Kutteh 1996b) until full term. Four trials initiated treatment at the first confirmation of pregnancy and treatment was continued until 34 weeks of gestation (Rai 1997), 35 weeks of gestation (Bao 2017; Laskin 2009) or study duration (Pattison 2000). One trial started aspirin before conception, with heparin (LMWH or UFH) started in the luteal phase for a maximum of three cycles

until delivery and continued postpartum in a prophylactic dose (Stephenson 2004).

Placebo

One trial randomised between aspirin and placebo (Pattison 2000). No studies were identified that compared heparin with placebo or aspirin and/or heparin with no treatment.

Outcomes reported

The reported outcomes per included trial are summarised in Table 2. Our primary outcome live birth was reported in all studies, in contrast to the secondary outcomes that were only reported in a subset of included trials. All included trials contributed data to at least one comparison in the meta-analysis.

1. Live birth rate: all 11 included trials reported our primary outcome live birth.
2. Pre-eclampsia: eight trials reported on pre-eclampsia (Alalaf 2012; Fouda 2010; Fouda 2011; Kutteh 1996a; Kutteh 1996b; Pattison 2000; Rai 1997; Stephenson 2004).
3. Maternal bleeding: eight trials mentioned maternal bleeding rates; three trials reported on postpartum haemorrhage or vaginal bleeding during pregnancy (Fouda 2010; Fouda 2011; Stephenson 2004), two trials reported on both major and minor maternal bleeding (Kutteh 1996a; Kutteh 1996b), one trial reported any maternal bleeding without specification (Pattison 2000) and two trials reported bruising at injection site in case of heparin use (Alalaf 2012, Fouda 2010).
4. Heparin-induced thrombocytopenia (HIT): 10 of 11 trials had heparin as an intervention arm and five trials reported on thrombocytopenia (Fouda 2010; Fouda 2011; Kutteh 1996a; Kutteh 1996b; Rai 1997).
5. Allergic reactions: one trial reported allergic reactions to study medication (Fouda 2011).
6. Venous thromboembolism (VTE): six trials reported on thromboembolic events, without discerning arterial or venous origin (Alalaf 2012; Fouda 2010; Fouda 2011; Kutteh 1996a; Laskin 2009; Rai 1997).
7. Arterial thromboembolism (ATE): six trials reported on thromboembolic events, without discerning arterial or venous origin (Alalaf 2012; Fouda 2010; Fouda 2011; Kutteh 1996a; Laskin 2009; Rai 1997).
8. Preterm delivery of a live infant: eight of 11 trials reported on preterm delivery of a live infant, defined as delivery between 32 to 37 weeks of gestation (Alalaf 2012), between 30 to 36 weeks or before 30 weeks (Farquharson 2002), between 24 to 37 weeks (Pattison 2000) or preterm was not specifically defined (Fouda 2010; Fouda 2011; Kutteh 1996a; Kutteh 1996b; Rai 1997).
9. Intrauterine growth restriction (IUGR): IUGR was reported in six of 11 studies (Fouda 2010; Fouda 2011; Kutteh 1996a; Kutteh 1996b; Pattison 2000; Rai 1997).
10. Congenital malformations: four trials reported on congenital malformations (Fouda 2010; Fouda 2011; Pattison 2000; Rai 1997).
11. Neonatal bleeding: two trials reported on neonatal bleeding (Fouda 2010; Fouda 2011).

Trial registries and dates

Only two of 11 trials had registered their study in a clinical trials registry (Laskin 2009; Fouda 2011), as at the time of publication for most of the other studies clinical trials registries were not operational. Three relatively more recent trials were published, but had not registered their study in a trials registry (Alalaf 2012; Bao 2017; Fouda 2010). More than half of the included studies were published before 2005. Three studies did not report on the recruitment period (Kutteh 1996a; Kutteh 1996b; Rai 1997), with one study only mentioning the overall recruitment time being 39 months (Pattison 2000).

Funding sources

Two trials were funded by governmental and non-governmental research grants from the UK (Farquharson 2002; Rai 1997), and two by governmental and non-governmental grants from Canada (Laskin 2009; Stephenson 2004). One study reported supply of study medication and sponsorship from a pharmaceutical company (Laskin 2009). One trial reported financial support by governmental research grants from China (Bao 2017). One study specifically thanked a pharmaceutical company for donation of study medication, but did not clarify the relationship (Stephenson 2004). Four trials did not mention any support (Fouda 2010; Kutteh 1996a; Kutteh 1996b; Pattison 2000).

Declarations of Interest

Five trials explicitly declared no conflict of interest (Alalaf 2012; Fouda 2010; Fouda 2011; Rai 1997; Stephenson 2004) and the other six trials did not state if any interests existed (Bao 2017; Farquharson 2002; Kutteh 1996a; Kutteh 1996b; Pattison 2000; Laskin 2009).

Excluded studies

Reasons for exclusion are stated in the Characteristics of excluded studies table. Eight studies were excluded based on abstract only, as full text could not be retrieved and information in the abstract was insufficient to critically evaluate if inclusion criteria were met (Bu 2009; Dendrinis 2007; Guo 2013; Malathi 2011; Malinowski 2003; Mankuta 1999; Quenby 1992; Zhou 2012). On obtaining the full papers, three trials were found to be non-randomised (Mohamed 2014; Noble 2005; Shefras 1995) and three trials had a different study design (Gibbins 2018; De Veciana 2001; Kahwa 2006). Eighteen trials considered a different study population, such as women without recurrent miscarriage or no persistent presence of aPL (Agarwal 2018; Cowchock 1997; De Vries 2012; Goel 2006; Golding 1998; Gris 1995; Ismail 2016; Kaaja 1993; Kaandorp 2010; Kahwa 2006; Mahmoud 2004; Radin 2017; Saad 2014; Tulppala 1997; Schisterman 2014; Vahid 1999; van Hoorn 2016; Visser 2011). Sixteen trials evaluated a different intervention or aspirin and/or heparin in combination with for instance intravenous immunoglobulin (IVIg) or prednisone (Branch 2000; Carta 2005; Christiansen 1995; Cowchock 1992; Dendrinis 2009; Eid 2019; Fu 2004; Geva 1998; Laskin 1997; Rai 2005; Shu 2002; Silver 1993; Tang 2012; Triolo 2003; Vaquero 2001; Xiao 2013). Two studies investigated a different outcome; thrombotic sequelae after 20 years (Clark 2009) and drug exposure throughout pregnancy (Ensom 2004), respectively.

Risk of bias in included studies

See [Figure 2](#); [Figure 3](#) for a summary of risk of bias in the included trials.

Figure 2. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

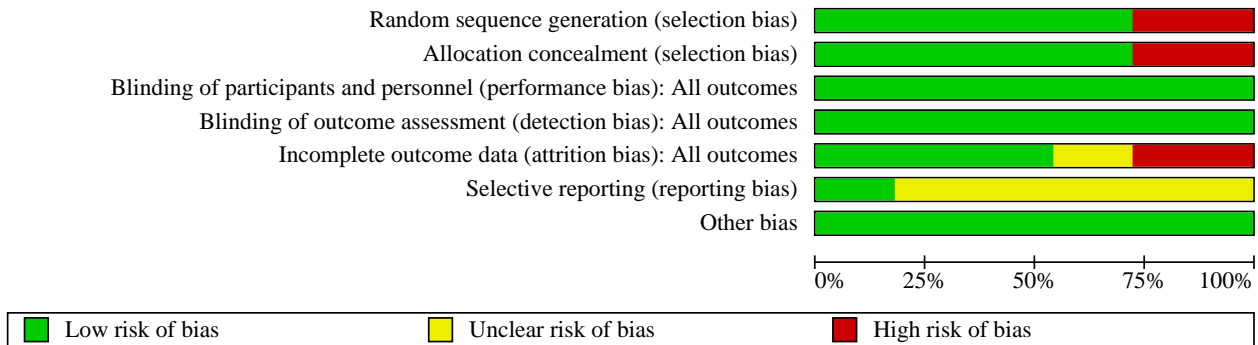

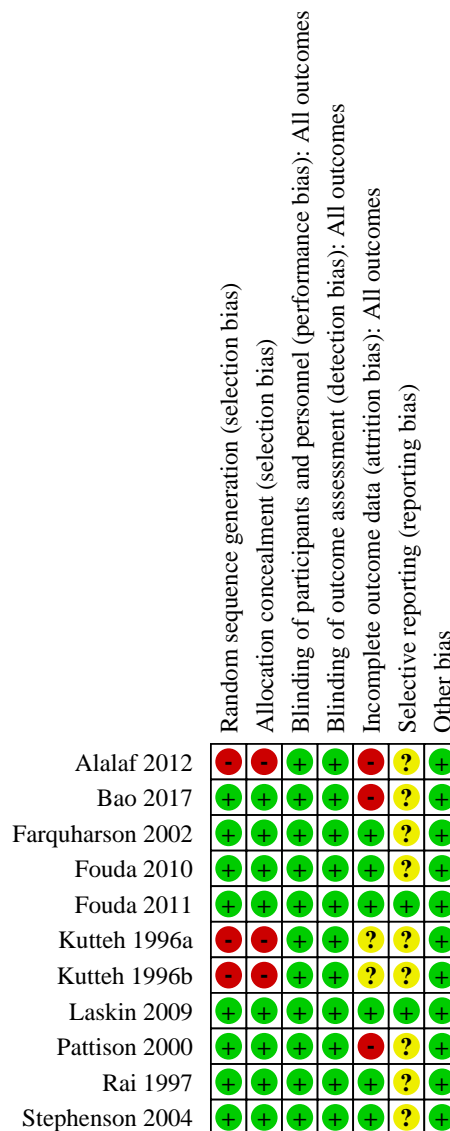

Figure 3. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

Allocation

Eight of 11 included trials, had low risk of bias for random sequence generation; seven trials used a computer-generated list of study numbers or other adequate methods of randomisation (Bao 2017; Farquharson 2002; Fouda 2010; Fouda 2011; Laskin 2009; Pattison 2000; Rai 1997) and one trial used a random numbers table with block of 12 (Stephenson 2004). One trial used some form of alternation, but the method of randomisation, or what treatment allocation was based on (e.g. date of birth or medical record number) was not described and therefore risk of bias is regarded as high (Alalaf 2012). Two quasi-randomised controlled trials used non-random alternative assignment to treatment groups (Kutteh 1996a) or a sequential block of 25 allocated to one treatment group and a second sequential block of 25 allocated to the other

treatment group (Kutteh 1996b) - both trials were assessed as high risk of bias.

Allocation concealment was considered adequate and thus at low risk of bias in eight of 11 studies (Bao 2017; Farquharson 2002; Fouda 2010; Fouda 2011; Laskin 2009; Pattison 2000; Rai 1997; Stephenson 2004) that used central or telephone randomisation or sealed, opaque envelopes. Three trials were assessed as high risk of bias - two quasi-randomised controlled trials did not conceal allocation of treatment (Kutteh 1996a; Kutteh 1996b), and one trial did not report methods to conceal allocation (Alalaf 2012).

Blinding

In only one trial both participant and treating physician were unaware of the treatment allocation (Pattison 2000). All other trials did not blind or did not report on blinding participants and treatment providers. Few trials stated explicitly who performed the outcome assessment and whether outcome assessors were blinded to treatment allocation. However, the primary outcome live birth was considered unlikely to be influenced by knowledge of treatment allocation, therefore these trials were assessed as low risk of bias, as suggested in the *Cochrane Handbook for Systematic Reviews for Interventions* (Higgins 2017).

Incomplete outcome data

The majority of trials had low rates of attrition and reasons for exclusion or the numbers of participants included in each stage of the analysis were clearly reported. Three trials were considered to be at high risk of attrition bias (Alalaf 2012; Bao 2017; Pattison 2000). Alalaf 2012 did not report on exclusions, reasons for exclusions, numbers included in the analysis at each stage or loss to-follow-up. Bao 2017, did a per-protocol analysis; 37 of the 1052 women receiving treatment failed to follow up or could not continue the trial due to change of intervention or specific allergies and outcomes of these censored participants were not reported; we assessed this trial as high risk of bias. In the trial by Pattison 2000, in each arm 5/25 (20%) of participants were excluded because of inappropriate inclusion. Analyses were performed with and without these participants but results from included participants only were published, not an analysis by intent-to-treat.

We assessed Kutteh 1996a and Kutteh 1996b as having an unclear risk of attrition bias; in those trials, exclusions, reasons for exclusion and numbers included in the analysis at each stage were not reported and it was unclear whether all evaluated participants started low-dose aspirin before conception, prior to randomisation. Also, analysis by intent-to-treat and losses to follow-up were unclear.

Selective reporting

Only a minority of trials were registered in a clinical trials registry and had a published study protocol (Fouda 2011; Laskin 2009), and we judged these trials to have a low risk of selective reporting. A clinical trial registry did not exist at the time of publication of some of the included studies (and for those more recently published studies, trial protocols were not available), and we therefore assessed reporting bias as unclear in eight unregistered studies, (Alalaf 2012; Bao 2017; Farquharson 2002; Fouda 2010; Kutteh 1996a; Kutteh 1996b; Rai 1997; Stephenson 2004). One trial excluded 20% of included participants due to inappropriate inclusion and performed analyses with and without these participants, but only provided results from included participants; we did not have sufficient information to assess whether all outcomes were reported and thus judged this trial to be at an unclear risk of reporting bias (Pattison 2000).

Other potential sources of bias

All of the included trials were assessed as low risk of other potential sources of bias.

Effects of interventions

See: [Summary of findings 1 Aspirin compared to placebo for improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss](#); [Summary of findings 2 Heparin plus aspirin compared to aspirin for improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss](#)

See: [Summary of findings 1](#); [Summary of findings 2](#)

Eleven trials (1672 women) met the inclusion criteria and all trials contributed data to our analyses. We present five different comparisons, with meta-analysis only possible in three of our comparisons; comparison 2 (heparin [UFH or LMWH] plus aspirin versus aspirin alone), comparison 4 (LMWH plus aspirin versus UFH plus aspirin) and comparison 5 (higher dose heparin [LMWH or UFH] plus aspirin versus lower dose heparin [LMWH or UFH] plus aspirin).

Comparison 1: Aspirin versus placebo

Primary outcome - Live birth

We are uncertain if there is any difference in live birth rates when comparing aspirin with placebo (risk ratio (RR) of 0.94, 95% confidence interval (CI) 0.71 to 1.25, 1 trial, 40 women; very low-certainty evidence; [Analysis 1.1](#); [Summary of findings 1](#)). In one small trial (Pattison 2000) there were similar numbers of live births in the aspirin group (16/20) and the placebo group (17/20).

Secondary outcomes (maternal)

Pre-eclampsia

We are uncertain if there is any difference in the risk of pre-eclampsia between aspirin and placebo (Pattison 2000; RR 1.06, 95% CI 0.25 to 4.52; 1 trial, 33 women; very low-certainty evidence; [Analysis 1.2](#); [Summary of findings 1](#)).

Adverse events in the mother (definitions according to original study: (A) bleeding, (B) heparin-induced thrombocytopenia, (C) allergic reactions)

It is uncertain if there is any difference in the risk of bleeding events during pregnancy when aspirin was compared with placebo (Pattison 2000; RR 1.29, 95% CI 0.60 to 2.77; 1 trial, 40 women; very low-certainty evidence; [Analysis 1.3](#); [Summary of findings 1](#)). Heparin-induced thrombocytopenia was not reported, as heparin was not evaluated in this trial; allergic reactions to aspirin or placebo were not reported either.

Venous thromboembolism

Not reported.

Arterial thromboembolism

Not reported

Pregnancy loss

We are very uncertain if there is any difference in the risk of pregnancy loss when comparing aspirin with placebo (RR 1.33, 95% CI 0.34 to 5.21; 40 women; 1 study; very low-certainty evidence; [Summary of findings 1](#); [Analysis 1.7](#)).

Secondary outcomes (for the child)

Preterm delivery of a live infant

It is uncertain if there is any difference between aspirin and placebo in the risk of preterm delivery did not occur in the 17 placebo-treated women and in two of 16 women receiving aspirin (Pattison 2000; RR 5.29, 95% CI 0.27 to 102.49; 1 trial, 33 children; very low-certainty evidence; Analysis 1.4; Summary of findings 1).

Intrauterine growth restriction (IUGR)

It is uncertain if there is any difference in the risk of IUGR between women receiving placebo or aspirin during pregnancy, the RR for IUGR was 0.27 (95% CI 0.03 to 2.13; 1 trial, 33 children; very low-certainty evidence; Analysis 1.5; Summary of findings 1),

Adverse events in the child (definitions according to original study: (A) congenital malformations, (B) neonatal bleeding)

It is uncertain if there is any difference between aspirin and placebo in the risk of adverse events. One child in both treatment groups was diagnosed with a congenital malformation in the trial of Pattison 2000, but malformations were not specified (RR 1.06; 95% CI 0.07 to 15.60; 1 trial, 33 children; very low-certainty evidence; Analysis 1.6; Summary of findings 1). Neonatal bleeding was not reported.

Comparison 2: Heparin plus aspirin versus aspirin alone

Primary outcome - Live birth

Five studies (1295 women) which compared heparin (either UFH or LMWH) combined with aspirin to aspirin alone, were included in a random-effects meta-analysis for the primary outcome live birth. Heparin plus aspirin may increase the number of live births compared with aspirin alone (RR 1.27; 95% CI 1.09 to 1.49; Tau² = 0.01; Chi² = 7.71, df = 4 (P = 0.10); I² = 48%; low-certainty evidence; Analysis 2.1; Summary of findings 2).

Subgroup analysis

We carried out a non-pre-specified subgroup analysis comparing trials that used LMWH and those that used UFH. There was evidence of a subgroup difference, as indicated by the subgroup interaction test (test for subgroup differences: Chi² = 4.74, df = 1 (P = 0.03), I² = 78.9%), possibly suggesting a larger treatment effect (benefit) with the use of UFH compared with LMWH. Both subgroups demonstrated higher rates of live birth when heparin was combined with aspirin as compared to aspirin alone (trials with LMWH: RR 1.20, 95% CI 1.04 to 1.38, 3 trials, 1155 women; trials with UFH: RR 1.74, 95% CI 1.28 to 2.35, 2 trials, 140 women; Analysis 2.1).

Farquharson 2002 reported 92.3% (12/13) pregnancy losses < 24 weeks of gestation and 7.7% (1/13) ≥ 24 weeks of gestation in the aspirin group, compared with all pregnancy losses in the LMWH plus aspirin group occurring before 24 weeks of gestation. All other included trials only reported total numbers of live birth.

We were not able to perform a subgroup analysis based on history of previous miscarriages, as three trials only included women with three or more recurrent pregnancy losses (Farquharson 2002; Kutteh 1996a; Rai 1997) and one trial explicitly stated that live birth did not differ between those with a history of two versus three pregnancy losses, without reporting numbers of participants (Laskin 2009). The largest trial did not report the numbers of previous miscarriages for participants in either

group, but described that this number (two versus three versus more than four) had no significant association with live birth (Bao 2017). Subgroup analyses based on previous placenta-mediated complications and positivity of lupus anticoagulant (LAC) antibodies were also not possible, since these were not specified for the primary outcome live birth, if reported at all. This also applied to a subgroup analysis based on aPL titers, with only one trial (Kutteh 1996a) reporting and no specification for live birth.

Sensitivity analysis

A sensitivity analysis excluding one quasi-randomised trial with a higher risk of bias (Kutteh 1996a) did not materially change the treatment effect. We did not carry out a sensitivity analysis to explore the effect of the full Sydney criteria for antiphospholipid syndrome (APS). Technically none of the participants in four trials met the current laboratory criteria for APS (positivity on two separate occasions, tested at least 12 weeks apart; Miyakis 2006), as the time between testing varied between six weeks (Farquharson 2002) and eight weeks (Laskin 2009; Rai 1997), or was undefined (Kutteh 1996a). The participants in the largest trial met the laboratory criteria, but it was unclear if the clinical criteria were met, as the trial did not differentiate between previous early and late pregnancy loss (Bao 2017).

Secondary outcomes (maternal)

Pre-eclampsia

It is uncertain if there is any difference in the risk of pre-eclampsia comparing UFH plus aspirin with aspirin alone (RR 0.57 95% CI 0.10 to 3.14; 2 trials, 82 women; low-certainty evidence; Analysis 2.2; Summary of findings 2).

Adverse events in the mother (definitions according to original study: (A) bleeding, (B) heparin-induced thrombocytopenia, (C) allergic reactions)

Major maternal bleeding was reported in one quasi-randomised controlled trial, but did not occur in any participant (Kutteh 1996a). It is uncertain if there is any difference in the risk of minor bleeding in the mother (RR 1.65; 95% CI, 0.19 to 14.03; 1 trial, 31 women; low-certainty evidence; Analysis 2.3), but this point estimate may not be reproduced in a larger sample size as implied by the wide confidence interval. Minor bleeding events, not further specified, did occur in 3/20 in the UFH and aspirin treated group, versus 1/11 in the aspirin only group. Data on heparin-induced thrombocytopenia and allergic reactions were collected, but none of the participating women reported either.

Venous thromboembolism

Three trials reported venous thromboembolism but none of the study participants was diagnosed with a new event during study participation (Kutteh 1996a; Rai 1997; Laskin 2009) (Analysis 2.4)..

Arterial thromboembolism

Three trials reported venous thromboembolism but none of the study participants was diagnosed with a new event during study participation (Kutteh 1996a; Rai 1997; Laskin 2009) (Analysis 2.5)

Pregnancy loss

Heparin plus aspirin may reduce the risk of pregnancy loss compared with aspirin alone (RR 0.48, 95% CI 0.32, 0.71; 1295

women; 5 studies; low-certainty evidence; [Summary of findings 2](#) ([Analysis 2.9](#)).

Secondary outcomes (for the child)

Preterm delivery of a live infant

It is uncertain if there is any difference in the risk of preterm delivery comparing heparin plus aspirin to aspirin alone (RR 0.93, 95% CI 0.42 to 2.07; 3 trials, 156 women; very low-certainty of evidence; [Summary of findings 2](#); [Farquharson 2002](#); [Kutteh 1996a](#), [Rai 1997](#); [Analysis 2.6](#)). [Farquharson 2002](#) specified preterm delivery at gestational age between 30 to 36 weeks (1/40 and 3/34 in the heparin plus aspirin and aspirin alone groups, respectively) and delivery before 30 weeks (1/40 and 1/34 in the heparin plus aspirin and aspirin alone groups respectively).

Intrauterine growth restriction

It is uncertain if there is any difference in the risk comparing heparin plus aspirin to aspirin alone (RR 0.85; 95% CI 0.33 to 2.19; 3 trials, 151 women; very low-certainty of evidence; [Summary of findings 2](#); [Analysis 2.7](#)).

Adverse events in the child (definitions according to original study: (A) congenital malformations, (B) neonatal bleeding)

The study of [Rai 1997](#) comparing UFH plus aspirin with aspirin alone found no congenital malformations in either treatment group ([Analysis 2.8](#)). Neonatal bleeding was not reported in any of the trials comparing a combination of heparin and aspirin with aspirin treatment alone.

Comparison 3: LMWH versus aspirin

Primary outcome - Live birth

We identified one study in which LMWH was compared with aspirin ([Alalaf 2012](#)). Women in the group treated with LMWH had a higher live birth rate of 86.3%, compared with a 72.1% live birth rate in the women treated with aspirin (RR 1.20, 95% CI 1.00 to 1.43, 1 trial, 141 women; [Analysis 3.1](#)).

Secondary outcomes (maternal)

Pre-eclampsia

One case of pre-eclampsia occurred in the LMWH-treated group, compared with none in the aspirin group (RR 1.93, 95% CI 0.08 to 46.31; [Analysis 3.2](#)).

Adverse events in the mother (definitions according to original study: (A) bleeding, (B) heparin-induced thrombocytopenia, (C) allergic reactions)

[Alalaf 2012](#) reported ecchymosis at injection site in 5 of 80 participants in the LMWH-treated group (RR 8.42, 95% CI 0.47 to 149.41; [Analysis 3.3](#), 1 trial, 141 women). Heparin-induced thrombocytopenia and allergic reactions to either LMWH or aspirin were not reported.

Venous thromboembolism

One trial reported zero events in both arms ([Alalaf 2012](#)) ([Analysis 3.4](#)).

Arterial thromboembolism

One trial reported zero events in both arms ([Alalaf 2012](#)) ([Analysis 3.5](#)).

Pregnancy loss

In one trial there were 11/80 pregnancy losses in the LMWH arm compared to 17/61 in the aspirin arm (RR 0.49, 95% CI 0.25, 0.98; [Analysis 3.7](#)).

Secondary outcomes (for the child)

Preterm delivery of a live infant

The rate of preterm delivery was low and no clear difference was observed between treatment groups in the trial that compared heparin alone to aspirin alone ([Alalaf 2012](#); RR 0.96, 95% CI 0.17 to 5.50, 1 trial, 113 women; [Analysis 3.6](#)).

Intrauterine growth restriction (IUGR)

IUGR was not reported as an outcome in the trial that compared heparin alone to aspirin alone ([Alalaf 2012](#)).

Adverse events in the child (definitions according to original study: (A) congenital malformations, (B) neonatal bleeding)

Neither congenital malformations nor neonatal bleeding were assessed in the trial by [Alalaf 2012](#).

Comparison 4: LMWH plus aspirin versus UFH plus aspirin

Primary outcome - Live birth

There was no clear difference between LMWH and aspirin versus UFH and aspirin for the outcome live birth (RR 1.44, 95% CI 0.80 to 2.62, 2 trials, 86 women; $\text{Tau}^2 = 0.11$; $\text{Chi}^2 = 1.91$, $\text{df} = 1$ ($P = 0.17$); $I^2 = 48\%$; [Analysis 4.1](#)) ([Fouda 2011](#); [Stephenson 2004](#)).

Secondary outcomes (maternal)

Pre-eclampsia

Pre-eclampsia occurred in three of 37 women in the LMWH plus aspirin treated group versus one woman of 33 in the UFH plus aspirin treated group (RR 2.09, 95% CI 0.33 to 13.22; [Analysis 4.2](#); [Fouda 2011](#); [Stephenson 2004](#)).

Adverse events in the mother (definitions according to original study: (A) bleeding, (B) heparin-induced thrombocytopenia, (C) allergic reactions)

Both the trials by [Fouda 2011](#) and [Stephenson 2004](#) did not establish any major bleeding events in either treatment group, but three of 30 women in each treatment arm in the trial by [Fouda 2011](#) reported subcutaneous bruises (RR 1.00, 95% CI 0.22 to 4.56, 2 trials, 206 women; [Analysis 4.3](#); [Fouda 2011](#); [Stephenson 2004](#)). Data on heparin-induced thrombocytopenia and allergic reactions were collected, but none of the participating women reported in the studies by [Fouda 2010](#); [Fouda 2011](#) reported either.

Venous thromboembolism

One trial reported zero venous thromboembolism events in both arms ([Fouda 2011](#)), whereas the trial by [Stephenson 2004](#) did not assess these ([Analysis 4.4](#)).

Arterial thromboembolism

One trial reported zero arterial thromboembolism events in both arms ([Fouda 2011](#)), whereas the trial by [Stephenson 2004](#) did not assess these ([Analysis 4.5](#)).

Pregnancy loss

Based on two studies, there may be a lower risk of pregnancy loss with LMWH plus aspirin compared to UFH plus aspirin (RR 0.53, 95% CI 0.28, 0.99; 83 women; [Analysis 4.9](#)).

Secondary outcomes (for the child)

Preterm delivery of a live infant

No clear difference in the risk of preterm delivery was observed with a higher compared with a lower dose of LMWH ([Analysis 4.6](#); [Fouda 2011](#)). This outcome could not be evaluated for different doses of UFH, as data were lacking.

Intrauterine growth restriction

The rates of IUGR in the trial by Fouda and colleagues were low, 1 of 24 in the higher dose of LMWH treatment arm versus 2 of 20 in the lower dose of LMWH treated group respectively (RR 0.42, 95% CI 0.04 to 4.27; [Analysis 4.7](#); [Fouda 2011](#)).

Adverse events in the child (definitions according to original study: (A) congenital malformations, (B) neonatal bleeding)

Both congenital malformations and neonatal bleeding were reported as an outcome, but the trial by [Fouda 2011](#) had no cases in either treatment arm ([Analysis 4.8](#)).

Comparison 5: Higher dose heparin plus aspirin versus lower dose heparin plus aspirin

Primary outcome - Live birth

A higher dose of LMWH did not improve the live birth rate (RR 1.10, 95% CI 0.81 to 1.49, 1 trial, 60 women; [Analysis 5.1](#)), similar to the effects of a higher dose of UFH (RR 1.05, 95% CI 0.78 to 1.41, 1 trial, 50 women; [Analysis 5.1](#)).

Secondary outcomes (maternal)

Pre-eclampsia

The incidence of pre-eclampsia did not clearly differ in the groups treated with a higher or a lower dose of either heparin (RR 1.64, 95% CI 0.41 to 6.48; [Analysis 5.2](#). 2 trials, 90 women; [Fouda 2010](#); [Kutteh 1996b](#)).

Adverse events in the mother (definitions according to original study: (A) bleeding, (B) heparin-induced thrombocytopenia, (C) allergic reactions)

Major maternal bleeding events did not occur in any participant, whereas the rate of minor bleeding events was similar in the high-dose UFH group (3/20) compared with the low-dose UFH group (4/19) (RR 0.71, 95% CI 0.18 to 2.77. 2 trials, 99 women; [Analysis 5.3](#); [Kutteh 1996b](#)). The incidence of postpartum haemorrhage was evaluated in one trial, but was not diagnosed ([Fouda 2010](#)). Heparin-induced thrombocytopenia was not reported in either trial, while allergic reactions were not assessed ([Fouda 2010](#); [Kutteh 1996b](#)).

Venous thromboembolism

[Fouda 2010](#) reported no events in any of the participants during study participation ([Fouda 2010](#); [Analysis 5.4](#)).

Arterial thromboembolism

[Fouda 2010](#) reported no events in any of the participants during study participation ([Fouda 2010](#); [Analysis 5.5](#)).

Pregnancy loss

Based on two studies, there may be a lower risk of pregnancy loss with LMWH plus aspirin compared to UFH plus aspirin (RR 0.80, 95% CI 0.41, 1.55; 110 women; [Analysis 5.9](#)).

Secondary outcomes (for the child)

Preterm delivery of a live infant

The rate of preterm delivery was low and the difference between treatment groups was not clear in the trials that compared a higher-dose heparin (LMWH or UFH) plus aspirin versus lower-dose heparin (LMWH or UFH) plus aspirin (RR 1.96, 95% CI 0.52 to 7.32; [Analysis 5.6](#); [Fouda 2010](#); [Kutteh 1996b](#)).

Intrauterine growth restriction

IUGR was reported in a small minority of cases and rates with no clear difference between interventions; 2/30 and 3/20 in the respective groups treated with a higher dose heparin (LMWH or UFH) versus 1/30 and 0/19 in the groups treated with a lower dose of heparin ([Fouda 2010](#); [Kutteh 1996b](#); [Analysis 5.7](#)).

Adverse events in the child (definitions according to original study: (A) congenital malformations, (B) neonatal bleeding)

Congenital malformations and neonatal bleeding were assessed in the trial by [Fouda 2010](#), but there were no cases in either treatment arm ([Fouda 2010](#); [Analysis 5.8](#)).

DISCUSSION

Summary of main results

The aim of this review was to assess the effects of aspirin or heparin or both for improving pregnancy outcome in women with persistent antiphospholipid antibodies (aPL) and recurrent pregnancy loss. There were no trials that had a no treatment comparator arm during pregnancy.

It is uncertain if aspirin alone has any effect on live birth when compared to placebo. There were no studies that investigated heparin alone.

The results of the meta-analyses suggest that the combination of heparin, started after a positive pregnancy test, plus aspirin may slightly improve live birth rates compared with aspirin alone. This result was mostly driven by one large single-centre trial (n = 1015) using low-molecular-weight heparin (LMWH), that found a 90.3% live birth rate in the LMWH plus aspirin group, compared to 70.1% in the group treated with aspirin alone. Two small trials evaluating unfractionated heparin (UFH) also demonstrated the combination of UFH plus aspirin to be superior to aspirin alone.

The pooled risk ratio for live birth in a head-to-head comparison of LMWH with UFH, both in combination with aspirin, did not demonstrate a clear benefit of one heparin over the other. Two small trials compared a higher and a lower dose of heparin (LMWH or UFH) both combined with aspirin, but there were insufficient data for meaningful analyses.

It is very uncertain if aspirin compared with placebo has any effect on the risk of pre-eclampsia, pregnancy loss, preterm delivery of a live infant, intrauterine growth restriction or adverse events in the mother or child.

Similarly, it is very uncertain if heparin plus aspirin compared with aspirin alone has any effect on the risk of pre-eclampsia, preterm delivery of a live infant, intrauterine growth restriction or adverse events in the mother or child.

Overall completeness and applicability of evidence

Eleven trials met our predefined inclusion criteria, with differences in treatment regimens and types of intervention. The substantial heterogeneity in study populations and numbers of enrolled participants reflect the clinical heterogeneity of antiphospholipid syndrome (APS) and at the same time point out the potential difficulties that can be encountered in conducting research in this population. The current review focused on recurrent pregnancy loss, whereas obstetric APS also has other manifestations. We strictly adhered to the inclusion criteria to maintain uniformity in this review and consequently excluded a large number of trials. Results from these trials may be of equal clinical importance and should not be neglected because they did not exactly meet the set criteria for the current review.

The evidence from this review stems from an overall small number of trials, though largely driven by the results from one trial with a large number of enrolled participants. The predefined criteria for inclusion and exclusion were followed consistently, though we broadened the criteria for persistent antibodies, as only three trials adhered to the time-frame of at least 12 weeks between aPL-testing. The heterogeneity in study populations, the variety of inclusion criteria and the interventions in the included trials form limitations in this review, but for the main comparisons findings were consistent.

Currently, suggested and widely employed management strategies to improve pregnancy outcomes in women with recurrent pregnancy loss and positive aPL include antepartum administration of prophylactic- or intermediate-dose UFH or prophylactic-dosed LMWH combined with aspirin over no treatment, but a risk and benefit evaluation per patient is advised (Bates 2012; Skeith 2018). The pharmacokinetic profiles of UFH and LMWH differ and perhaps their biological effects as well. Possible effects on complement activation may be of more importance and it has been hypothesised that the non-anticoagulant effects of heparins on inflammatory processes, vascular function or placental pathology may play a role in prevention of pre-eclampsia, a disorder highly associated with APS (Wat 2018). In a mouse model of the APS, the prevention of fetal loss by both LMWH and UFH was mediated through complement activation inhibition (Girardi 2004). A prophylactic dose of LMWH was sufficient to reduce classical complement activity in pregnant women with a history of venous thromboembolism, but this has not been evaluated for different dosages of heparin, or in presence of aPL (Oberkersch 2010). The role of non-thrombotic processes involved in the pathogenesis of recurrent miscarriage in presence of aPL has become more clear over the years (Schreiber 2018). As defined in the protocol, we planned to carry out a subgroup analysis based on a history of previous placenta-mediated complications, such as pre-eclampsia, intrauterine growth restriction and/or placental abruption. The rationale for this was the different pathogenesis of recurrent early

(i.e. first-trimester) miscarriage associated with presence of aPL from the pathogenesis of aPL-associated late pregnancy morbidity. A minority of trials reported our predefined secondary outcomes and a subgroup analysis was not possible for this reason.

Clinical criteria for pregnancy morbidity associated with APS include ≥ 1 unexplained fetal death after ≥ 10 weeks of gestation, one or more premature delivery < 34 weeks of gestation due to severe (pre)eclampsia or placental insufficiency or ≥ 3 unexplained consecutive miscarriages < 10 weeks of gestation. Though all participants in the included studies had at least two, and most at least three pregnancy losses and persistent presence of aPL, baseline characteristics differed largely between study populations. A substantial part of the studied population in the current review are not considered to be patients with obstetric APS and it is known that differences exist in risk for obstetric complications in subgroups of patients with APS (Meroni 2012; Lockshin 2013; Schreiber 2018). Most of our studied population differs from women described as being a classic APS case (late fetal death, lupus anticoagulant, history of thrombosis). In obstetric APS, presence of lupus anticoagulant has been identified as the main predictor of adverse pregnancy outcomes and thrombotic events (Buyon 2015, Lockshin 2012). As demonstrated in Table 1, in patients whose aPL antibody profiles were reported, the majority of the studied population was positive for lupus anticoagulant alone or both lupus anticoagulant and anticardiolipin antibodies. Bao 2017 reported results on a large number of women with aPL and recurrent miscarriage, but did not report details on aPL-profiles in either treatment group; therefore it remains unknown if clinically relevant subgroup differences exist. Attempts to contact the authors of this trial in order to retrieve additional data relevant for the current review, were unfruitful. This trial also did not exclude patients with a previous thrombosis, whereas most other trials explicitly did. We ourselves did not further define miscarriage, as both recurrent early or late pregnancy losses could be included (as long as a history of two miscarriages had been established) and only a minority of the studies reported additional data on gestational age at the time of pregnancy loss. Hence, patients with classic APS may have been included in the studied population. We cannot state that the risk for obstetric complications or thrombotic complications for that matter, is much lower in our studied population, as we simply lack the data to conclude this.

As the main predictor for the next pregnancy outcome is the number of previous pregnancy losses (Carp 2007), possibly the trial by Laskin and colleagues (Laskin 2009) would have demonstrated different outcomes for subgroups with ≥ 2 or ≥ 3 previous miscarriages. The largest trial (Bao 2017), which was a large contributor to the pooled effect, included women with a history of at least two consecutive miscarriages, but did not report the number of previous miscarriages per treatment group. It should be noted that the currently employed Sydney classification criteria for APS (Miyakis 2006) form an aid in the diagnosis of APS, but were originally developed for research purposes. In the current review, we were not able to carry out subgroup analyses based on aPL-profiles, due to the small numbers of included trials and/or limited reporting of aPL-profiles in correlation to the primary outcome live birth.

Antibody cut-off levels differed greatly between trials and only one trial explicitly reported aPL-titres in participants. The association between aPL and recurrent pregnancy loss varies per type of aPL

and also differs for early and late pregnancy loss (Opatrny 2006). For this reason, current guidelines recommend testing for aPL (lupus anticoagulant (LAC) and anticardiolipin (ACA) IgG and IgM) after two pregnancy losses, consecutive or non-consecutive, whereas testing for a β_2 GPI can be considered (Vermeulen 2018). None of the included trials in the current review reported women with a β_2 -GPI antibodies. Clinical studies ideally should report results on women with homogenous aPL-profiles and women with strongly positive tests or high-titre antibodies should be analysed separately. As APS is a heterogeneous disease with a wide variation in both clinical presentation and laboratory parameters, an accurate evaluation of two interventions in a homogeneous subset of APS-patients is challenging.

Uncertainty also remains regarding the ideal timing of initiation and duration of treatment. Most trials included in this review started eligible participants on aspirin preconceptionally, with heparin added once pregnancy was confirmed, in order to compare heparin and/or aspirin with aspirin alone during pregnancy. A recent study by Eid 2019 evaluated early initiation of LMWH, i.e. once positive pregnancy test was established in the fifth week of gestation, and later initiation of LMWH, i.e. after sonographic confirmation of fetal cardiac pulsation in week seven, both regimens combined with aspirin started preconceptionally. Early initiation led to an ongoing pregnancy rate of 81% at 12 weeks' gestation compared to 61% in the later initiation group. However, live birth rates and the incidence of late obstetrical complications were similar in both groups (Eid 2019). In another trial, comparing LMWH and aspirin with placebo given preconceptionally, women in the treatment group had a higher ongoing pregnancy rate within six months after randomisation when compared with women in the placebo group, but live birth overall was not affected. Additionally, the incidence of pre-eclampsia was higher in the placebo-treated women; 24% versus 11% in the intervention group (Ismail 2016). Initiation of heparin preconceptionally in all women with APS and recurrent early pregnancy loss would be undesirable from a patients' perspective, but whether heparin can be safely discontinued after the first trimester of pregnancy with regard to pregnancy outcome, requires further investigation.

Women with persistent presence of aPL and a history of thrombosis as well as recurrent miscarriage require thromboprophylaxis during pregnancy, as aspirin only would not be considered sufficient to prevent recurrent thrombosis. However, there are no randomised clinical trials that have evaluated anticoagulant treatment strategies, i.e. between different doses of anticoagulants, in this high-risk population. In women with obstetric APS without a personal history of venous or arterial thrombosis receiving antepartum anticoagulant prophylaxis continuation postpartum can be considered (Bates 2018). However, the incidence of postpartum thrombosis in this population is unclear, hence the aim of postpartum thromboprophylaxis and duration thereof in this population, cannot be substantiated with the currently available evidence. Further trials should investigate the role of LMWH for prevention of recurrent pregnancy loss and of placenta-mediated complications in women with APS.

In the trial by Farquharson 2002, a substantial part of the study population was non-adherent (24/98), which challenges interpretation of the reported results. The authors reported no significant differences in live birth in the non-adherent group compared to either the adherent group or the whole group.

Adherence to therapy may have been higher in women receiving UFH- compared to LMWH-treated women, as the dose of UFH is adjusted per patient through activated partial thromboplastin time (aPTT) monitoring. The optimal dose of LMWH or heparin, with maximal benefit and minimal risks, is unknown. Various doses of aspirin and or heparin were used in the included studies, but we did not account for these differences in the analyses, due to small sizes of the studies and limited data. Studies comparing a high or low dose of either UFH or LMWH in combination with aspirin did not show significant differences between treatment groups, though it should be noted that the quasi-randomised controlled trial comparing different dosages of UFH lacked the power to detect any significant differences and had methodological limitations (no allocation concealment). Variation in initiation of treatment, in duration of treatment, as well as different doses and agents used, limits the possibilities of a cross-study comparison. Two included trials continued heparin postpartum.

Noticeably, adverse events associated with heparin therapy, easy bruising at injection site or allergies, did not occur frequently or were not reported. The improvement in pregnancy outcome observed in the UFH-treated women seemed to be associated with a non-significant increase in risk of preterm delivery, as assessed in the subgroup of live births. For intrauterine growth restriction a comparison in the subgroup of live births was not possible, as the trial by Laskin at al (Laskin 2009) only reported adverse outcomes for all participants. As we do not know the baseline risk for preterm delivery and intrauterine growth restriction in the subgroups of live birth and this baseline risk likely differs, this comparison is prone to bias.

Important side effects of UFH therapy, such as haemorrhage and heparin-induced thrombocytopenia did not occur or were not reported and only minor bleeding events and bruising at injection site were mentioned as possible adverse effects of heparin therapy. In the general population (i.e. without anticoagulant use during pregnancy), estimated incidences of bleeding after delivery > 500 mL typically range from 4% to 6% (Scheres 2019). Hence, the possibility of underreporting should be considered in interpreting these figures. Thrombocytopenia occurs in 5% to 10% of all pregnant women, with a slow decrease in platelet counts starting in the second trimester, most likely a consequence of haemodilution (Cines 2017). Osteoporosis is associated with heparin treatment and should be taken into consideration when treatment is long term, but was not evaluated as a secondary outcome in this review. UFH therapy when given in a low dose does not require monitoring and likely is effective in preventing recurrent pregnancy loss, though the unexpectedly low live birth rates in the comparator arms in the UFH studies may have led to an overestimation of the effect. LMWH, which has a similar efficacy and a superior safety profile compared with UFH, is a reasonable alternative treatment and currently most often used in clinical practice.

Quality of the evidence

Most of the trials were judged to be at low risk of bias for most categories. Two quasi-randomised trials were at high risk of selection bias due to lack of allocation concealment (Kutteh 1996a; Kutteh 1996b), and in one trial, allocation concealment was unclear, therefore considered as at high risk of selection bias as well (Alalaf 2012). Three trials reported incomplete outcome data (attrition bias), including one trial at high risk for reporting bias as well (Alalaf 2012; Bao 2017; Pattison 2000).

Additionally, a majority of trials were not registered in a clinical trial registry nor had published a study protocol. For this reason, it remains unclear whether selective reporting occurred in these trials and we assessed reporting bias as unclear in unregistered studies published in the last 10 years.

Though in only two trials participants and personnel both were made unaware of treatment allocation, we assessed all trials at low risk for performance bias, since live birth is an unequivocal outcome and knowledge of treatment allocation is unlikely to influence this.

Certainty of the evidence

The certainty of evidence is low to very low. We downgraded the evidence for imprecision (due to low numbers of women participating in the studies and wide 95% confidence intervals, which are consistent with appreciable harms and benefits) and for risk of bias limitations.

Potential biases in the review process

We minimised the risk of bias in the selection of studies, with an extensive search strategy and no language or publication date restriction, to identify all relevant studies. Two review authors independently assessed study eligibility, performed data extraction and GRADE assessments. There was no funding provided for this review. Lastly, none of the review authors were involved in any of the trials evaluated for this review. We were unaware of any potential bias by focusing specifically on aspirin and/or heparin versus placebo or another for prevention of recurrent pregnancy loss in women with persistent aPL in this revision of the previous review. Formal assessment of reporting bias by means of a funnel plot, was not possible due to the small number of trials in the meta-analyses for the main comparisons.

Agreements and disagreements with other studies or reviews

For aspirin, we only identified one study which investigated the effect of aspirin alone by comparing it with placebo (Pattison 2000). However, due to its small sample size and considerable limitations, no conclusions could be drawn based on this single study. In studies with women with recurrent pregnancy loss without persistent aPL, aspirin does not seem to improve live birth rates (De Jong 2014). Aspirin has been studied extensively in the context of reduction of the risk of pre-eclampsia. Here, also outside of the population with persistent aPL, aspirin reduces the risk of pre-eclampsia (Askie 2007; Rolnik 2017). Based on the lack of direct evidence and available indirect evidence, it is reasonable to suggest aspirin for prevention of pre-eclampsia in women with recurrent pregnancy loss and persistent aPL.

A cohort study of 693 women with recurrent miscarriage evaluated live birth rates in aPL-positive women and in women with unexplained recurrent miscarriage; overall live birth rates were 69% in aPL-positive women and 63% in women with unexplained recurrent miscarriage. Stratification by treatment demonstrated 79% live birth in the group with aPL-positive women treated with aspirin and heparin compared to 62% in the group treated with aspirin alone. Stratification by treatment did not show differences in outcome in the group of women with recurrent miscarriage (Cohn 2010). In non-aPL populations evidence from an individual-

patient level meta-analysis suggests no role for LMWH in a prophylactic dose during pregnancy to prevent recurrent placenta-mediated pregnancy complications (Rodger 2014). Another recent meta-analysis including eight trials involving 483 women with inherited thrombophilia and recurrent miscarriage found no significant difference in live birth rates with LMWH use compared to no LMWH (RR 0.81, 95% CI 0.55 to 1.19) (Skeith 2016).

AUTHORS' CONCLUSIONS

Implications for practice

Heparin (low-molecular-weight heparin (LMWH) or unfractionated heparin (UFH)) combined with aspirin may lead to more live births in women with recurrent pregnancy loss with antiphospholipid antibodies (aPL) than treatment with aspirin alone (low-certainty evidence). The observed beneficial effect of heparins is mainly driven by one large single-centre trial using LMWH. The effect of aspirin on live birth rates remains uncertain.

Implications for research

A large multicentre randomised controlled trial with clearly defined inclusion and exclusion criteria for subgroups of patients with aPL and recurrent pregnancy loss, is needed in order to evaluate risks and benefits of current treatment strategies and to gain consensus on the ideal prevention for recurrent pregnancy loss, based on a risk profile. Additionally, further research involving women with obstetric antiphospholipid syndrome (APS) without a history of venous or arterial thrombosis, is needed to determine whether LMWH can be safely discontinued after the first trimester of pregnancy, with regard to adverse pregnancy outcomes.

ACKNOWLEDGEMENTS

CHARACTERISTICS OF STUDIES
Characteristics of included studies [ordered by study ID]

Alalaf 2012
Study characteristics

Methods	Open-label, randomised controlled trial (N = 141)
Participants	<p><u>Inclusion criteria</u></p> <ol style="list-style-type: none"> age 18-42 years at time of interview ≥ 2 unexplained consecutive miscarriages before 20 weeks' gestation persistent presence of aCL antibodies (IgG > 15 GPL or IgM > 25 MPL) or positive LAC on 2 occasions, 8 weeks apart. <p><u>Exclusion criteria</u></p> <p>Systemic lupus erythematosus, known peptic ulcer disease, sensitivity to aspirin or heparin depending on patient's history report, previous venous thromboembolic disease requiring ongoing anticoagulant therapy, other causes for recurrent miscarriage (polycystic ovarian syndrome, thyroid dysfunction, anatomical causes), bacterial vaginosis infection and failure to consent to participate.</p>
Interventions	LMWH (bemiparin) 2500 IU/day sc (N = 80)

Aspirin or heparin or both for improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss (Review)
33

Alalaf 2012 (Continued)

versus

Aspirin 100 mg/day (N = 61)

Outcomes	<u>Primary outcome</u> Live birth <u>Secondary outcomes</u> Obstetrical complications, fetal and maternal adverse events
Notes	<p>Aspirin commenced preconceptionally until 36 weeks of gestation, bempiparin commenced when pregnancy was confirmed until 36 weeks of gestation.</p> <p>Mean number of previous pregnancy losses was 3.28 ± 1.72 in the LMWH group versus 3.41 ± 1.76 in the aspirin group; no specification for previous early and late loss reported.</p> <p>As study outcome total pregnancy loss reported; no specification for early and late loss reported.</p> <p>Trial registry: trial not registered in clinical trial registry. No published study protocol. Dates of study: recruitment period 15 September 2007 to 1 August 2010, publication 2012. Funding sources: not stated Declarations of interest: none</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	Process of randomisation not clearly described. Authors state some form of alternation between treatment groups: the first case was randomised to treatment 1, the second case to treatment 2 and sometimes 2 cases were randomised to treatment 1, followed by one case of treatment 2.
Allocation concealment (selection bias)	High risk	Not reported.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Incomplete outcome data (attrition bias) All outcomes	High risk	Exclusions, reasons for exclusion and numbers included in the analysis at each stage were not reported. Loss-to-follow up not reported.
Selective reporting (reporting bias)	Unclear risk	Trial not registered in clinical trial registry. No published study protocol.
Other bias	Low risk	No indication of other sources of bias

Bao 2017
Study characteristics

Aspirin or heparin or both for improving pregnancy outcomes in women with persistent antiphospholipid antibodies and recurrent pregnancy loss (Review)

34

Bao 2017 (Continued)

Methods	Randomised study (N = 1096)
Participants	<p><u>Inclusion criteria</u></p> <p>1) history of ≥ 2 consecutive miscarriages</p> <p>2) ≥ 2 blood tests taken at an interval of at least 12 weeks apart confirming the presence of either LA (prolongation of the dilute Russell viper venom time ratio greater than 1.09 with at least 20% correction by washed, frozen/thawed platelets) anti-β2GPI or aCL antibodies (IgG > 40 GPL, IgM > 40 MPL or higher than the 99th percentile of the reference range obtained with normal participants) before pregnancy</p> <p><u>Exclusion criteria</u></p> <p>Recent history of major surgery; pregnancy; haemorrhage or trauma; under oral contraception or hormone therapy; partner with an abnormal karyotype</p>
Interventions	<p>LMWH (nadroparin) 4100 U/day sc + aspirin 75 mg/day (N = 497)</p> <p><i>versus</i></p> <p>Aspirin 75 mg/day (N = 518)</p>
Outcomes	Live birth and pregnancy failure (including ectopic pregnancy and miscarriage)
Notes	<p>At confirmation of pregnancy randomisation to either LMWH + aspirin or aspirin, treatment continued until miscarriage or 35 weeks of gestation.</p> <p>Number of previous pregnancy losses not reported.</p> <p>As study outcome total pregnancy loss reported; no specification for early and late loss reported.</p> <p>Per-protocol analysis, no intention-to-treat analysis.</p> <p>30/548 in LMWH + aspirin group and 14/548 in aspirin group excluded due to disagreement on assigned treatment. Additionally, 37 (3.3%) women lost to follow-up (21/518 in LMWH + aspirin group and 16/534 in aspirin group).</p> <p>497 women in LMWH + aspirin group versus 518 women in aspirin group.</p> <p>Trial registry: trial not registered in clinical trial registry. No published study protocol.</p> <p>Dates of study: recruitment period 2012 to 2015, publication in 2017.</p> <p>Funding sources: Shanghai Committee of Science and Technology, Grant/Number: 14411966600 and 17411967800; The Joint Key Project of New Frontier Technology in Shanghai Municipal Hospitals, Grant/Number: SHDC12014129.</p> <p>Declarations of interest: not stated</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated randomisation list.
Allocation concealment (selection bias)	Low risk	Adequate allocation concealment, randomisation list kept by independent member of staff not involved in the trial.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.

Bao 2017 (Continued)

Blinding of outcome assessment (detection bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Incomplete outcome data (attrition bias) All outcomes	High risk	No published study protocol. Exclusions, reasons for exclusion and numbers included in the analysis at each stage were reported; loss to follow-up reported; per-protocol analysis, outcomes of censored participants and reasons for censoring unclear.
Selective reporting (reporting bias)	Unclear risk	Trial not registered in clinical trial registry. No published study protocol.
Other bias	Low risk	No indication of other sources of bias

Farquharson 2002
Study characteristics

Methods	Single-centre, randomised non-blinded, non-placebo controlled trial (N = 98)
Participants	<p><u>Inclusion criteria</u></p> <p>1) 18-41 years</p> <p>2) ≥ 3 consecutive pregnancy losses or 2 consecutive losses with proven fetal death after 10 weeks</p> <p>3) 2 positive test for antiphospholipid antibodies more than 6 weeks apart, determined by lupus anticoagulant (dRVVT > 1.09 with > 20% correction with platelets), or aCL antibodies (IgG > 9 U/mL or aCL IgM > 5 U/mL)</p> <p><u>Exclusion criteria</u></p> <p>Parental chromosomal abnormality, uterine anomaly, previous arterial or venous thrombosis, use of steroids during pregnancy, systemic lupus erythematosus requiring medication or complicated by nephritis, and other thrombophilia such as activated protein C resistance or protein C/S deficiency.</p>
Interventions	<p>LMWH 5000 IU/day sc + aspirin 75 mg/day (N = 51)</p> <p><i>versus</i></p> <p>Aspirin 75 mg/day (N = 47)</p>
Outcomes	Embryo loss (no visible crown rump length or fetal heart activity) and fetal loss (loss of fetal heart activity after clear identification on previous scan)
Notes	<p>Randomisation occurred < 12 weeks' gestation, mean 7.1 weeks for LMWH plus aspirin group and 6.3 weeks for the aspirin group</p> <p>Mean number of previous pregnancy losses was 3 ± 0.8 in the LMWH + aspirin group versus 3 ± 0.9 in the aspirin group; no specification for previous early and late loss reported.</p> <p>LMWH plus aspirin or aspirin started at randomisation (before 12 weeks of gestation) and continued until delivery.</p> <p>11/47 in the aspirin group also took LMWH and 13/51 in the aspirin/LMWH group took aspirin alone</p> <p>Type of LMWH not specified.</p>

Farquharson 2002 (Continued)

11/51 pregnancy losses in the LMWH plus aspirin group (3/11 embryo loss, 8/11 fetal loss) versus 13/47 pregnancy losses in the aspirin group (9/13 embryo loss, 4/13 fetal loss).

Trial registry: trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol.

Dates of study: recruitment period from January 1997 to January 2000, publication in 2002.

Funding sources: LUPUS UK and NHS R&D (NWEST) grant support

Declarations of interest: not stated

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated sequence of random numbers.
Allocation concealment (selection bias)	Low risk	Telephone randomisation, adequate allocation concealment.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth
Blinding of outcome assessment (detection bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth Data collection by independent research officer who received copies of randomisation data sheets. Blinding of outcome assessment not explicitly stated.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Exclusions, reasons for exclusion and numbers included in the analysis at each stage were reported; no missing outcome data, no loss to follow-up.
Selective reporting (reporting bias)	Unclear risk	All analyses completed on an intention-to-treat basis. Trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol.
Other bias	Low risk	No indication of other sources of bias

Fouda 2010
Study characteristics

Methods	2-arm prospective, randomised controlled study (N = 60)
Participants	<p><u>Inclusion criteria</u></p> <p>1) ≥ 3 consecutive pregnancy losses before 10 weeks' gestation</p> <p>2) positive LAC and/or aCL antibodies (IgG and IgM) on at least 2 occasions, at least 12 weeks apart</p> <p><u>Exclusion criteria</u></p> <p>Paternal chromosomal abnormalities or uterine abnormalities, luteal phase defect, abnormal thyroid function tests, hyperprolactinaemia, polycystic ovary syndrome, systemic lupus erythematosus, pre-</p>

Fouda 2010 (Continued)

vious thromboembolism, peptic ulcer, age < 19 years or > 37 years, BMI < 19 or > 30 or sensitivity to aspirin or heparin.

Interventions	LMWH (enoxaparin) 40 mg/day sc + aspirin 75 mg/day (N = 30) <i>versus</i> LMWH (enoxaparin) 20 mg/day sc + aspirin 75 mg/day (N = 30)
Outcomes	<p><u>Primary outcome</u></p> <p>Live birth rate</p> <p><u>Secondary outcome</u></p> <p>Maternal and obstetric complications during pregnancy or puerperium such as excessive bleeding, thrombocytopenia, intrauterine growth restriction, pre-eclampsia, intrauterine fetal death, thrombotic event and spontaneous osteoporotic fractures. For the infants preterm delivery, neonatal bleeding and congenital anomalies.</p>
Notes	<p>All participants were started on aspirin preconceptionally until 36 weeks and LMWH was added with a confirmed positive pregnancy test and continued until delivery.</p> <p>Mean number of previous pregnancy losses was 4.03 ± 1.24 in the LMWH 40 mg + aspirin group versus 4.1 ± 1.12 in the LMWH 20 mg plus aspirin group; no specification for previous early and late loss reported.</p> <p>7/30 pregnancy losses in the LMWH 40 mg + aspirin group (6/30 first trimester loss, 1/30 second trimester loss) versus 9/30 pregnancy losses in the LMWH 20 mg + aspirin group (8/30 first trimester loss, 1/30 second trimester loss). No intrauterine fetal death in either group.</p> <p>Trial registry: trial not registered in clinical trial registry. No published study protocol. Dates of study: recruitment period December 2008 to May 2010, publication 2010. Funding sources: not stated Declarations of interest: none</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random numbers.
Allocation concealment (selection bias)	Low risk	Opaque envelopes.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinding not reported, but knowledge of treatment allocation unlikely to influence outcome live birth.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Exclusions, reasons for exclusion and numbers included in the analysis at each stage were reported; no loss to follow-up, all participants analysed.

Fouda 2010 (Continued)

Selective reporting (reporting bias)	Unclear risk	Trial not registered in clinical trial registry. No published study protocol.
Other bias	Low risk	Nothing to indicate any other sources of bias.

Fouda 2011
Study characteristics

Methods	2-arm, prospective, open-labelled, multicentre, randomised controlled trial (N = 60)
Participants	<p><u>Inclusion criteria</u></p> <p>1) ≥ 3 consecutive pregnancy losses before 10 weeks' gestation</p> <p>2) Positive anticardiolipin antibodies IgG (> 40 GPL) and IgM (> 40 MPL) or presence of LAC (aPTT and dilute Russell viper venom test). All of the women with positive LAC and/or anticardiolipin antibodies were retested after at least 12 weeks. Only those with persistently positive tests were included in the study.</p> <p><u>Exclusion criteria</u></p> <p>Paternal chromosomal abnormalities; uterine malformation detected by hysterosalpingography or office hysteroscopy; cervical incompetence; luteal-phase defect; abnormal thyroid function tests; hyperprolactinaemia; polycystic ovary syndrome; hereditary thrombophilia; systemic lupus erythematosus; previous venous or arterial thrombotic episodes; diabetes mellitus; kidney or liver disease; gastric ulcer; and sensitivity to aspirin, UFH, or enoxaparin.</p>
Interventions	<p>Unfractionated heparin 5000 U sc twice daily + aspirin 75 mg/day (N = 30)</p> <p><i>versus</i></p> <p>LMWH (enoxaparin) 40 mg/day sc + aspirin 75 mg/day (N = 30)</p>
Outcomes	<p><u>Primary outcome</u></p> <p>Live birth rate</p> <p><u>Secondary outcomes</u></p> <p>Excessive haemorrhage (defined by a 10% decline in the hematocrit value or the requirement of a blood transfusion), thrombocytopenia (platelet count $\leq 100,000$/mL), IUGR (birthweight lower than the tenth percentile for gestational age), pre-eclampsia (blood pressure $\geq 140/90$ mm Hg and proteinuria ≥ 300 mg/day), IUFD, and spontaneous osteoporotic fractures. For the infants, the secondary endpoints were preterm labour (birth of infant at < 37 weeks of gestation), neonatal bleeding, and congenital anomalies.</p>
Notes	<p>Multicentre trial (2 centres). All women became pregnant after randomisation. Aspirin was started before conception and continued through pregnancy until 36 weeks of gestation. Anticoagulation treatment was started as soon as the serum pregnancy test became positive.</p> <p>Mean number of previous pregnancy losses was 4.37 ± 1.19 in the UFH + aspirin group versus 4.23 ± 1.16 in the LMWH + aspirin group; no specification for previous early and late loss reported.</p> <p>10/30 pregnancy losses in the UFH + aspirin group (9/30 first trimester loss, 1/30 second trimester loss) versus 6/30 pregnancy losses in the LMWH + aspirin group (6/30 first trimester loss, 0/30 second trimester loss). No intrauterine fetal death in either group.</p> <p>Trial registry: the study was registered at clinicaltrials.gov [NCT01051778].</p>

Fouda 2011 (Continued)

Dates of study: recruitment period 28 June 2006 to 14 December 2009, publication 2011.

Funding sources: not stated

Declarations of interest: none

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated randomisation list.
Allocation concealment (selection bias)	Low risk	Sequentially-numbered, opaque sealed envelopes, each containing the allocation information written on a card. The envelopes were opened sequentially by a staff nurse to assign the women to either treatment group. The computer-generated randomisation list and the sealed envelopes were prepared by a statistician not involved in the study.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinding not reported, but knowledge of treatment allocation unlikely to influence outcome live birth.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Exclusions, reasons for exclusion and numbers included in the analysis at each stage were reported; no loss to follow-up, all participants analysed.
Selective reporting (reporting bias)	Low risk	The study was registered at clinicaltrials.gov [NCT01051778]. All of the study's pre-specified outcomes and all expected outcomes of interest were reported.
Other bias	Low risk	Multicentre trial (2 centres).

Kutteh 1996a
Study characteristics

Methods	Single-centre, quasi-randomised, non-blinded, non-placebo controlled trial (N = 50)
Participants	<p><u>Inclusion criteria</u></p> <ol style="list-style-type: none"> 1) Desire to become pregnant 2) Agreement to be completely evaluated 3) ≥ 3 spontaneous consecutive miscarriages 4) Consent to alternative treatment assignment 5) Presence of antiphospholipid antibodies ≥ 27 IgG or ≥ 23 IgM phospholipid units (> 2.5 multiples of the median) on 2 separate occasions <p><u>Exclusion criteria</u></p>

Kutteh 1996a (Continued)

Systemic lupus erythematosus, positive for lupus anticoagulant, presence of another abnormal test result that was not corrected either medically or surgically, aspirin allergy, another reason for anticoagulation during pregnancy, refused treatment or assignment to treatment.

Interventions	Unfractionated heparin 5000 units sc twice daily + aspirin 81 mg/day (N = 25) <i>versus</i> Aspirin 81 mg/day (N = 25)
Outcomes	Obstetric complications (preterm birth, intrauterine growth retardation and maternal complications (gestational diabetes, major and minor bleeding, thrombocytopenia, pre-eclampsia)
Notes	Aspirin commenced before conception, heparin commenced at the first confirmed pregnancy test (5.3 weeks post-gestation). Treatment was continued until delivery and heparin continued for 3 weeks postpartum. Heparin dose increased by 1000 units/dose weekly until PTT was 1.2-1.5 times baseline. Mean total prior miscarriages per patient was 3.9 ± 1.4 in the UFH + aspirin group (79.1% of these < 12 weeks of gestation, 91.3% < 20 weeks of gestation) versus 3.7 ± 1.0 in the aspirin group (76.6% of these < 12 weeks of gestation, 88.5% < 20 weeks of gestation). As study outcome total pregnancy loss reported; no specification for early and late loss reported. Trial registry: trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol. Dates of study: recruitment period not specified, publication in 1996. Funding sources: not stated Declarations of interest: not stated Authors report that treatment was initiated at the first documented pregnancy test, to eliminate selection bias.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	Non-random alternative assignment of treatment.
Allocation concealment (selection bias)	High risk	No concealment of allocation.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	600 women evaluated, 50 consented to study participation; exclusions, reasons for exclusion and numbers included in the analysis at each stage were not reported. Unclear whether all evaluated participants started low-dose aspirin before conception, prior to randomisation. Analysis by intent-to-treat and loss to follow-up unclear.

Kutteh 1996a (Continued)

Selective reporting (reporting bias)	Unclear risk	Trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing, therefore unclear risk. No published study protocol.
Other bias	Low risk	No indication of other sources of bias

Kutteh 1996b
Study characteristics

Methods	Single-centre, quasi-randomised, non-blinded, non-placebo controlled trial (N = 50)
Participants	<p><u>Inclusion criteria</u></p> <ol style="list-style-type: none"> 1) Desire to become pregnant 2) Agreement to be completely evaluated 3) ≥ 3 documented pregnancy losses 4) Presence of antiphospholipid antibodies IgG ≥ 27 GPL (> 2.5 multiples of the median) on 2 separate occasions 5) Consent to treatment protocol <p><u>Exclusion criteria</u></p> <p>Systemic lupus erythematosus, a positive test for lupus anticoagulant, an allergy to aspirin, a documented bone disorder, another abnormal test result that was not corrected aspirin allergy, refused treatment.</p>
Interventions	<p>Aspirin 81 mg/day plus heparin 5000 U twice daily sc adjusted to maintain the PTT at 1.2 to 1.5 times the baseline (high dose) (N = 25)</p> <p><i>versus</i></p> <p>Aspirin 81 mg/day + heparin 5000 U twice daily sc adjusted to maintain the PTT at the upper limit of normal (low dose) (N = 25)</p>
Outcomes	Obstetric complications (preterm birth, intrauterine growth retardation and maternal complications (gestational diabetes, major and minor bleeding, thrombocytopenia, pre-eclampsia)
Notes	<p>Mean daily dose in low-dose heparin group 8127 ± 2389 U twice daily; mean daily dose in high-dose heparin group 13300 ± 3500 U twice daily.</p> <p>Aspirin commenced before conception, heparin commenced at the first confirmed pregnancy test. Treatment was continued until delivery and heparin continued for 3 weeks postpartum.</p> <p>Mean total prior miscarriages per patient was 3.6 ± 1.0 in the low-dose UFH + aspirin group (92.9% of these < 20 weeks of gestation) versus 3.9 ± 1.4 in the aspirin group (91.2% of these < 20 weeks of gestation).</p> <p>As study outcome total pregnancy loss reported; no specification for early and late loss reported.</p> <p>Trial registry: trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol.</p> <p>Dates of study: recruitment period not specified, publication in 1996.</p> <p>Funding sources: not stated</p> <p>Declarations of interest: not stated</p>

Kutteh 1996b (Continued)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	The first 25 women had heparin dosages adjusted periodically to maintain the baseline PTT at 1.2 to 1.5 times baseline (HD heparin). The second 25 women had heparin dosages adjusted periodically to maintain the PTT at the allocated to upper limits of the normal range (LD heparin).
Allocation concealment (selection bias)	High risk	No concealment of allocation.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding not reported, but knowledge of treatment allocation unlikely to influence outcome live birth.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinding not reported, but knowledge of treatment allocation unlikely to influence outcome live birth.
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Over 750 women evaluated, 50 consented to study participation; exclusions, reasons for exclusion and numbers included in the analysis at each stage were not reported. Unclear whether all evaluated participants started low-dose aspirin before conception, prior to randomisation. Analysis by intent-to-treat and loss to-follow-up unclear.
Selective reporting (reporting bias)	Unclear risk	Trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing, therefore unclear risk. No published study protocol.
Other bias	Low risk	No indication of any other source of bias.

Laskin 2009
Study characteristics

Methods	Open-label randomised controlled trial (N = 88). Subgroup with aPL antibodies N = 42
Participants	<p><u>Inclusion criteria</u></p> <ol style="list-style-type: none"> aged 18 to 44 years at time of randomisation history of ≥ 2 unexplained consecutive pregnancy losses prior to 32 weeks' gestation presence of at least 1 of the following: ANA, antiphospholipid antibodies (aCL IgG > 15 GPL or IgM > 25 MPL and/or LAC positivity, tested on 2 occasions at least 8 weeks apart), or an inherited thrombophilia confirmed pregnancy by either 2 appropriately rising quantitative beta human chorionic gonadotropin (beta hCG) tests performed 48 hours apart or by ultrasound confirming fetal heart activity <p><u>Exclusion criteria</u></p> <p>Systemic lupus erythematosus (fulfilling American College of Rheumatology classification criteria), known peptic ulcer disease (within the last 5 years), sensitivity to aspirin or heparin obtained by self-report, bone mineral density z score < -2.5, known platelet function abnormality, previous thromboembolic event requiring ongoing anticoagulant therapy including heparin/aspirin/warfarin verified in medical records, genetic/anatomic/hormonal aetiology for pregnancy loss was identified by (re-</p>

Laskin 2009 (Continued)

spectively) karyotype analysis of both partners, hysterosalpingogram/sonohysterogram, and a hormonal evaluation (which included either an endometrial biopsy or loss while taking progesterone or clomiphene therapy or mid luteal phase serum progesterone levels timed appropriately), geographic distance from the clinic and hospitals in Toronto/Hamilton, failure to consent.

Interventions	LMWH (dalteparin) 5000 U/day sc + aspirin 81 mg/day (N = 22) versus Aspirin 81 mg/day (N = 20)
Outcomes	Live birth
Notes	<p>42 of 88 randomised participants had persistent presence of antiphospholipid antibodies, of whom 22 were randomised to LMWH + aspirin and 20 were randomised to aspirin alone.</p> <p>Aspirin and LMWH started at randomisation (after confirmed pregnancy) and continued until 35 weeks of gestation.</p> <p>Authors have been contacted to provide information on the secondary outcomes for the subgroup of aPL-positive participants</p> <p>32/45 in the LMWH + aspirin group had a history of early losses (≤ 14 weeks of gestation) versus 34/43 in the aspirin group.</p> <p>4/45 in the LMWH + aspirin group had a still birth (20-32 weeks of gestation) versus 7/43 in the aspirin group.</p> <p>Pregnancy loss in 10/45 in the LMWH + aspirin group (7/10 ≤ 14 weeks of gestation, 2/10 ectopic pregnancy, 1 stillbirth) versus 9/43 in the aspirin group (8/9 ≤ 14 weeks of gestation, 1 stillbirth).</p> <p>Trial registry: study registered at clinicaltrials.gov [NCT 00564174] Dates of study: recruitment period 2000-2004, publication in 2009. Funding sources: Canadian Institute of Health Research (CIHR) Rx&D grant (PCT 37749) and by a grant from Pfizer Canada (formerly Pharmacia, Canada). LMWH was supplied by Pfizer Canada. Declarations of interest: not stated</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Central randomisation. Stratified by presence or absence of aPL, and early (≤ 14 weeks) versus late (15-32 weeks) losses. Women with history of both early and late losses were assigned to the late stratum.
Allocation concealment (selection bias)	Low risk	Adequate allocation concealment; central randomisation, communication by telephone.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth
Blinding of outcome assessment (detection bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth
Incomplete outcome data (attrition bias) All outcomes	Low risk	Exclusions, reasons for exclusion and numbers included in the analysis at each stage were reported; no loss to follow-up, all participants analysed.

Laskin 2009 (Continued)

Selective reporting (reporting bias)	Low risk	Study registered at clinicaltrials.gov [NCT 00564174]. All of the study's pre-specified outcomes and all expected outcomes of interest were reported.
Other bias	Low risk	Multicentre trial (2 centres).

Pattison 2000
Study characteristics

Methods	Single-centre, double-blind, randomised, placebo-controlled trial (N = 40)	
Participants	<u>Inclusion criteria</u> 1) ≥ 3 miscarriages 2) persistent positive aPL antibody pre-pregnancy or early during index pregnancy; anticardiolipin antibodies IgG ≥ 5 GPL units or IgM ≥ 5 MPL units or presence of LAC (aPTT, dRVVT or KCT). <u>Exclusion criteria</u> History of thrombosis, systemic lupus erythematosus, current or planned therapy with corticosteroids, NSAIDs, heparin or marine lipids.	
Interventions	Aspirin 75 mg/day (N = 20) <i>versus</i> Placebo (N = 20)	
Outcomes	Live birth, antenatal outcomes (bleeding, hypertension, preterm birth, caesarean delivery) and neonatal outcomes (birthweight, small-for-gestational age, neonatal admission, congenital anomalies)	
Notes	Randomisation after confirmation of pregnancy, if antiphospholipid antibodies were positive before pregnancy or detected during pregnancy. Aspirin and placebo commenced 50 and 44 days respectively after last menstrual period, duration of treatment was not defined. Overall percentage of previous pregnancy losses 80.7% in the aspirin group versus 74.8% in the placebo group. Median first-trimester losses 3 (interquartile range 1.5) in the aspirin group versus 4.5 (3) in the placebo group. As study outcome total pregnancy loss reported; no specification for early and late loss reported. Trial registry: trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol. Dates of study: recruitment over a period of 39 months, no further specification. Publication in 2000. Funding sources: not stated Declarations of interest: not stated	

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated list of study numbers.

Pattison 2000 (Continued)

Allocation concealment (selection bias)	Low risk	Sealed envelopes.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Blinding by placebo.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Blinding by placebo.
Incomplete outcome data (attrition bias) All outcomes	High risk	In each arm 5/25 (20%) of participants were excluded because of inappropriate inclusion. Analyses were performed with and without these participants but results from included participants only published. No analysis by intent-to-treat. No loss to follow-up.
Selective reporting (reporting bias)	Unclear risk	Results from included participants only published. Insufficient data to assess whether all outcomes were reported. Trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol.
Other bias	Low risk	No indication of any other source of bias.

Rai 1997
Study characteristics

Methods	Single-centre, randomised, non-blinded, non-placebo controlled trial (N = 90)
Participants	<p><u>Inclusion criteria</u></p> <p>1) history of ≥ 3 consecutive miscarriages</p> <p>2) positive antiphospholipid antibodies on at least 2 occasions more than 8 weeks apart before becoming pregnant, determined by anticardiolipin antibodies IgG ≥ 5 GPL or IgM ≥ 3 MPL or a positive LAC (aPTT, dRVVT ratio ≥ 1.1 confirmed by platelet neutralisation - decrease of $\geq 10\%$ of ratio).</p> <p><u>Exclusion criteria</u></p> <p>Previous thromboembolism, systemic lupus erythematosus, uterine abnormality detected on ultrasound, hypersecretion of luteinising hormone, multiple pregnancy, abnormal karyotype of either partner.</p>
Interventions	<p>Unfractionated heparin 5000 U twice daily sc + aspirin 75 mg/day (N = 45)</p> <p><i>versus</i></p> <p>Aspirin 75 mg/day (N = 45)</p>
Outcomes	Live birth
Notes	<p>Aspirin commenced in all participants after positive pregnancy test. Heparin commenced in heparin only group after randomisation.</p> <p>Randomisation occurred when fetal heart activity was noted on ultrasound (6.6 weeks in aspirin group and 6.7 weeks in aspirin/heparin group).</p> <p>Treatment continued until 34 weeks of gestation.</p>

Rai 1997 (Continued)

Median number of previous miscarriages was 4 (range 3 to 15) in the heparin + aspirin group versus 4 (range 3 to 8) in the aspirin group. 29/45 in the heparin + aspirin group had first trimester miscarriages only, 13/45 first and second trimester miscarriages. 31/34 in the aspirin group had first trimester miscarriages only, 13/45 first and second trimester miscarriages.

13/45 pregnancy losses in the UFH + aspirin group (median gestational age at miscarriage 9.4 weeks, 11/13 < 14 weeks of pregnancy) versus 26/45 in the aspirin group (median gestational age at miscarriage 8.3 weeks, 24/26 < 14 weeks of pregnancy).

Trial registry: trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol.

Dates of study: recruitment period not specified, publication in 1997.

Funding sources: Arthritis and Rheumatism Council UK

Declarations of interest: none

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random number list
Allocation concealment (selection bias)	Low risk	Central randomisation
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth
Blinding of outcome assessment (detection bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth
Incomplete outcome data (attrition bias) All outcomes	Low risk	Exclusions, reasons for exclusion and numbers included in the analysis at each stage were reported; no loss to follow-up. All participants remained in their originally allocated treatment group and outcome of all pregnancies were analysed.
Selective reporting (reporting bias)	Unclear risk	Trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol.
Other bias	Low risk	No indication of any other source of bias.

Stephenson 2004
Study characteristics

Methods	Randomised pilot trial (N = 28). Subgroup of participants that conceived (N = 26)
Participants	<p><u>Inclusion criteria</u></p> <ol style="list-style-type: none"> 1) history of ≥ 3 unexplained recurrent miscarriages of earlier than 10 weeks' gestation 2) persistently positive antiphospholipid antibodies; anticardiolipin antibodies IgG or IgM or lupus anticoagulant, drawn at least 6 weeks apart <p><u>Exclusion criteria</u></p>

Stephenson 2004 (Continued)

Parental structural chromosome abnormality, anatomical factor (uterine septum, intrauterine adhesions, submucous fibroid), concomitant inherited thrombophilia, prior heparin use.

Interventions	<p>Aspirin 81 mg/day preconceptionally + LMWH (dalteparin) 2500 IU once daily sc luteal phase; after conception aspirin 81mg/day + LMWH (dalteparin) 2500 IU once daily sc in first trimester, 5000 IU once daily sc in second trimester, 7500 IU once daily sc in third trimester (N = 13)</p> <p><i>versus</i></p> <p>Aspirin 81 mg/day preconceptionally + unfractionated heparin 5000 IU twice daily sc in luteal phase; after conception aspirin 81 mg/day + unfractionated heparin 5000 IU twice daily sc first trimester, 7500 IU sc twice daily second trimester, 10,000 IU twice daily sc third trimester (N = 13)</p>
Outcomes	Live birth
Notes	<p>Aspirin was instituted preconceptionally and continued indefinitely. Heparin was started in the luteal phase for a maximum of 3 cycles and continued 6 weeks postpartum.</p> <p>13 of 14 women randomised to dalteparin had at least 1 pregnancy in the trial, 13 of 14 women randomised to UFH had at least 1 pregnancy in the trial.</p> <p>1 woman in the dalteparin group and 2 women in the UFH group had a second pregnancy while trial in progress. 3 women in the UFH group had a third pregnancy and 1 woman in the UFH group had a 4th pregnancy while trial in progress.</p> <p>Mean number of previous miscarriages in the aspirin plus LMWH group 3.8 (range 3 to 7) versus 3.9 (range 3 to 7) in the aspirin plus UFH group. As study outcome total pregnancy loss reported; no specification for early and late loss reported.</p> <p>Trial registry: trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol.</p> <p>Dates of study: recruitment period June 1998 to March 2001, publication 2004.</p> <p>Funding sources: British Columbia Medical Services Foundation grant support and Pharmacia Canada donation of Fragmin.</p> <p>Declarations of interest: none</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random numbers table with blocks of 12.
Allocation concealment (selection bias)	Low risk	Central randomisation.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	No blinding, but knowledge of treatment allocation unlikely to influence outcome live birth.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Exclusions and reasons for exclusion were reported. The numbers included in the analysis at each stage (compared with the total randomised participants) were reported. Missing data were balanced across groups.

Stephenson 2004 (Continued)

Selective reporting (reporting bias)	Unclear risk	Trial not registered in clinical trial registry, but clinical trial registry at time of publication non-existing. No published study protocol.
Other bias	Low risk	No indication of any other source of bias.

aCL: anticardiolipin; **aPL:** antiphospholipid antibodies; **aPTT:** activated partial thromboplastin time; **BMI:** body mass index; **GPI:** glycoprotein-1; **GPL:** IgG phospholipids; **IgG:** immunoglobulin G; **IgM:** immunoglobulin M; **IU:** international units; **IUFD:** Intrauterine fetal death; **IUGR:** Intrauterine growth restriction; **LAC:** lupus anticoagulant; **LMWH:** low-molecular-weight heparin; **MPL:** IgM phospholipids; **NSAIDs:** nonsteroidal anti-inflammatory drugs; **PTT:** partial thromboplastin time; **SC:** subcutaneous; **UFH:** unfractionated heparin.

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Agarwal 2018	Different study population: women with inherited thrombophilia, no APS
Branch 2000	Different intervention: heparin + low-dose aspirin + intravenous immunoglobulin <i>versus</i> heparin + low-dose aspirin + placebo
Bu 2009	Abstract only; unclear whether randomised study or persistent presence of antiphospholipid antibodies. Insufficient data available to determine study eligibility.
Carta 2005	Different intervention: low-dose aspirin <i>versus</i> fish oil derivatives
Christiansen 1995	No antiphospholipid antibodies detected and different intervention (intravenous immunoglobulin)
Clark 2009	Different outcome: thrombotic sequelae after 20 years
Cowchock 1992	Different intervention: low-dose heparin <i>versus</i> prednisone 40 mg daily
Cowchock 1997	No associated signs or symptoms of the antiphospholipid antibody syndrome, i.e. no recurrent pregnancy loss
De Veciana 2001	Prospective longitudinal study, with different study population (women treated with prophylactic anticoagulation throughout pregnancy) and different study outcome (increase in LMWH dose, both dosing frequency and total daily dose)
De Vries 2012	Women with antiphospholipid antibodies randomised into a separate study
Dendrinis 2007	Abstract only, different study population: women with a history of recurrent pregnancy loss and at least 1 factor of thrombophilic disorder, APS not specified. Insufficient data available to determine study eligibility.
Dendrinis 2009	Different intervention: LMWH + low-dose aspirin <i>versus</i> intravenous immunoglobulin
Eid 2019	Evaluation of different timing of initiation of low-molecular weight heparin administration during pregnancy; early LMWH initiation once positive pregnancy test (week 5 of gestation) <i>versus</i> late LMWH initiation after sonographic confirmation of fetal cardiac pulsation (week 7 of gestation).
Ensom 2004	Different study population: women with APS contemplating pregnancy, obstetric APS or recurrent miscarriage not specified Different outcome: drug exposure throughout pregnancy
Fu 2004	Different intervention: aspirin + prednisone <i>versus</i> heparin

Study	Reason for exclusion
Geva 1998	Different intervention: prednisone 10 mg + aspirin 100 mg daily versus no treatment Different endpoint: in-vitro fertilisation embryo transfer failure
Gibbins 2018	Different study design: cohort study
Goel 2006	No persistent presence of antiphospholipid antibodies
Golding 1998	Different study population: primiparae, no APS, no recurrent miscarriage Different outcome: occurrence of pre-eclampsia and intrauterine growth retardation
Gris 1995	Different study population: primary early recurrent unexplained miscarriages, antiphospholipid antibody positive excluded Different intervention: enoxaparin versus phenformin-like substance Different outcome: fibrinolytic response, number of patients becoming pregnant, number of full-term pregnancies
Guo 2013	No abstract or full text retrievable; unclear whether randomised study. Insufficient data available to determine study eligibility.
Ismail 2016	Evaluation of pre-conception thromboprophylaxis: LMWH plus aspirin pre-conception versus placebo pre-conception. All patients received LMWH plus aspirin once pregnancy was confirmed.
Kaaja 1993	Different study population: pregnant women with systemic lupus erythematosus Different intervention: production of prostacyclin and thromboxane
Kaandorp 2010	Women with unexplained recurrent miscarriage, no APS
Kahwa 2006	Prevalence survey with a different study population (primiparae, no APS, no recurrent miscarriage)
Kim 1997	Different intervention: aspirin versus aspirin + prednisolone
Laskin 1997	Different intervention: prednisone + aspirin <i>versus</i> placebo
Mahmoud 2004	Different study population: women with recurrent pregnancy loss, no antiphospholipid antibodies Different intervention: intravenous IgG Different outcome: effects of IgG infusion on peripheral T-cell subpopulations
Malathi 2011	Abstract only; no full text retrievable. Unclear whether persistent presence of antiphospholipid antibodies. Insufficient data available to determine study eligibility.
Malinowski 2003	Abstract only, no full text retrievable. Unclear whether persistent presence of antiphospholipid antibodies. Insufficient data available to determine study eligibility.
Mankuta 1999	Abstract only, no full text retrievable. Different intervention (prednisone) according to abstract.
Mohamed 2014	Non-randomised study
Noble 2005	Prospective, non-randomised, controlled pilot study
Quenby 1992	Abstract only, quasi-randomised and missing information (history of recurrent fetal loss not available). Insufficient data available to determine study eligibility.

Study	Reason for exclusion
Radin 2017	Different study population: healthy women attempting pregnancy, with regular menstrual cycles and had a history of 1 to 2 documented pregnancy losses, ≤ 2 live births, and no infertility Different intervention: aspirin 81mg daily for 1 to 6 menstrual cycles Different outcome: per-cycle risk of anovulation
Rai 2005	Different study intervention: low-dose steroid + aspirin + heparin versus aspirin + heparin
Saad 2014	Different study population: women with unexplained recurrent pregnancy loss, no antiphospholipid antibodies
Schisterman 2014	Women with 1 or 2 pregnancy losses, APS an exclusion criterion
Shefras 1995	Different study design: non-randomised Different outcome: bone density
Shu 2002	Abstract only, no full text retrievable. According to abstract different intervention: Chinese herbal medicine + human chorionic gonadotropin and progesterone versus multi-vitamin only
Silver 1993	Different intervention: prednisone + low dose aspirin versus aspirin alone
Tang 2012	Different intervention: aspirin + prednisone versus aspirin + heparin
Triolo 2003	Different intervention: low-molecular-weight heparin + aspirin versus intravenous immunoglobulin
Tulppala 1997	Different study population: women with and without detectable anticardiolipin antibodies, no persistent presence of aPL Different outcome: prostacyclin and thromboxane A2 production
Vahid 1999	Different study population: women with unexplained recurrent abortions, no APS Different intervention: acetylsalicylic acid and prednisolone before and during pregnancy
van Hoorn 2016	Recurrent pregnancy loss not an inclusion criterion
Vaquero 2001	Different intervention: prednisone + low-dose aspirin <i>versus</i> intravenous immunoglobulin
Visser 2011	Women with or without thrombophilia, no antiphospholipid antibodies
Xiao 2013	Different intervention: prednisone + aspirin versus prednisone + aspirin + LMWH + intravenous immunoglobulin Different study design: clinical comparative study
Zhou 2012	No abstract or full text retrievable; unclear whether randomised study. Insufficient data available to determine study eligibility.

aPL: antiphospholipid antibodies; **APS:** antiphospholipid syndrome; **IgG:** immunoglobulin; **LMWH:** low-molecular-weight heparin.

Characteristics of ongoing studies [ordered by study ID]

Abdelhafez 2014

Study name	Use of warfarin after the first trimester in pregnant women with antiphospholipid syndrome
Methods	Open-label randomised controlled trial
Participants	<p><u>Inclusion criteria</u></p> <p>1) 20-38 years of age</p> <p>2) Pregnant women with APS diagnosed according to the revised classification criteria for APS in 2006 in Sydney, Australia</p> <p>3) Early pregnancy body weight is 50 kg to 90 kg</p> <p><u>Exclusion criteria</u></p> <p>Systemic lupus erythematosus, active or a history of thromboembolic disorders</p>
Interventions	Enoxaparin (LMWH) 40 mg/day sc <i>versus</i> enoxaparin 40 mg/day sc in first trimester, then warfarin (3 mg/day to 5 mg/day) until termination of pregnancy
Outcomes	<p><u>Primary outcome</u></p> <p>Fetal loss from 20 to 42 weeks gestational age</p> <p><u>Secondary outcomes</u></p> <p>Preterm delivery from 20 to 34 weeks gestational age, intrauterine growth restriction at birth, congenital fetal malformations at birth, haemorrhagic complications after 12 weeks gestational age up to birth, thromboembolic complications after 12 weeks gestational age up to birth</p>
Starting date	November 2014
Contact information	<p>Principal Investigator: Dr. Mohamed I Eid - Mansoura University, Egypt</p> <p>Study Director: Dr. Mohamed S Abdelhafez - Mansoura University, Egypt</p>
Notes	NCT02303171

Rodger 2017

Study name	Antiphospholipid syndrome low-molecular-weight heparin pregnancy loss evaluation: the pilot study (APPLE)
Methods	Randomised controlled trial (feasibility study)
Participants	<p><u>Inclusion criteria</u></p> <p>1) Confirmed pregnancy</p> <p>2) 18 years or older</p> <p>3) 2 or more unexplained pregnancy loss before the 10th week of gestation, AND/OR 1 or more unexplained pregnancy loss at or beyond the 10th week of gestation</p> <p>4) 1 or more APS laboratory criteria present, according to the revised Sapporo criteria</p> <p><u>Exclusion criteria</u></p> <p>Greater than 11 weeks + 6 days gestational age at time of randomisation, indication(s) for prophylactic or therapeutic-dose anticoagulation, contraindication to heparin or aspirin, received 7 or</p>

Rodger 2017 (Continued)

	more doses of LMWH, previous participation in the trial, geographic inaccessibility, refused consent.
Interventions	Tinzaparin (LMWH) 4500 IU sc daily until 20 weeks' gestation and then 4500 IU sc twice daily until 37 weeks' gestation + aspirin 81 mg daily <i>versus</i> aspirin 81 mg daily until delivery
Outcomes	The primary feasibility outcome of the pilot trial is the mean recruitment rate per centre per month.
Starting date	November 6, 2017
Contact information	Principal Investigator: Marc Rodger, MD - Ottawa Hospital Research Institute, Canada Principal Investigator: Leslie Skeith, MD - Ottawa Hospital Research Institute, Canada
Notes	NCT03100123

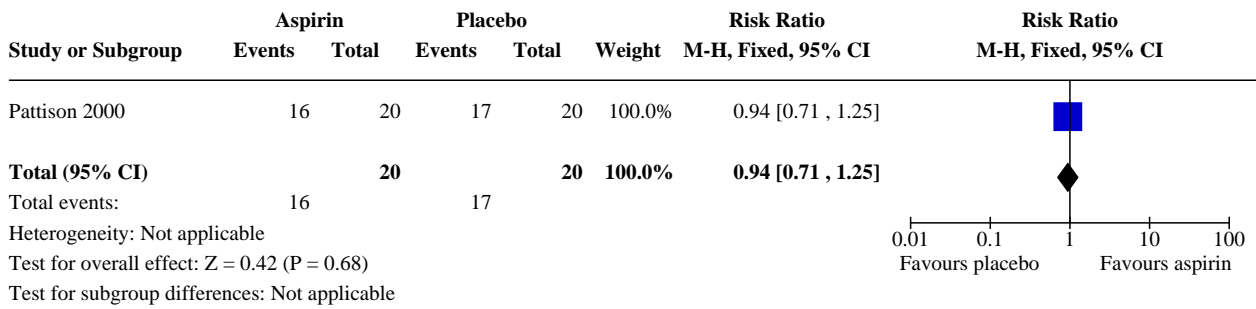

APS: antiphospholipid syndrome; **IU:** international units; **LMWH:** low-molecular-weight heparin; **sc:** subcutaneous.

DATA AND ANALYSES

Comparison 1. Aspirin versus placebo

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.1 Live birth	1	40	Risk Ratio (M-H, Fixed, 95% CI)	0.94 [0.71, 1.25]
1.2 Pre-eclampsia	1	33	Risk Ratio (M-H, Fixed, 95% CI)	1.06 [0.25, 4.52]
1.3 Adverse events in the mother	1		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
1.3.1 Bleeding	1	40	Risk Ratio (M-H, Fixed, 95% CI)	1.29 [0.60, 2.77]
1.4 Preterm delivery of a live infant	1	33	Risk Ratio (M-H, Fixed, 95% CI)	5.29 [0.27, 102.49]
1.5 Intrauterine growth restriction	1	33	Risk Ratio (M-H, Fixed, 95% CI)	0.27 [0.03, 2.13]
1.6 Adverse events in the child	1		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
1.6.1 Congenital malformations	1	33	Risk Ratio (M-H, Fixed, 95% CI)	1.06 [0.07, 15.60]
1.7 Pregnancy loss	1	40	Risk Ratio (M-H, Fixed, 95% CI)	1.33 [0.34, 5.21]

Analysis 1.1. Comparison 1: Aspirin versus placebo, Outcome 1: Live birth

Analysis 1.2. Comparison 1: Aspirin versus placebo, Outcome 2: Pre-eclampsia

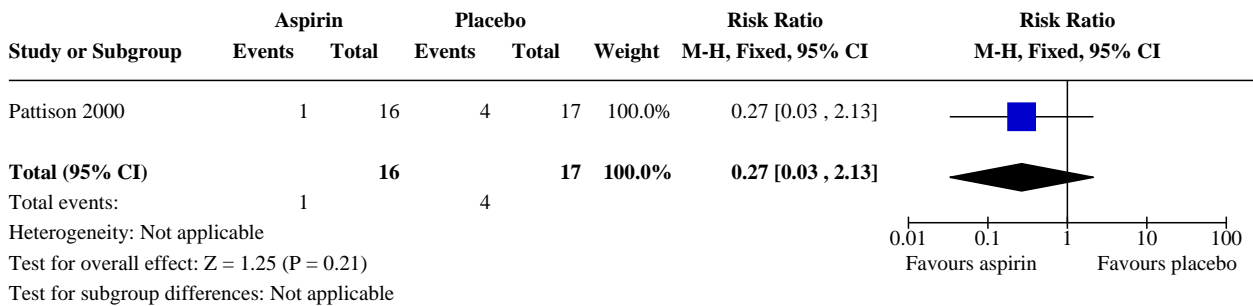

Analysis 1.3. Comparison 1: Aspirin versus placebo, Outcome 3: Adverse events in the mother

Analysis 1.4. Comparison 1: Aspirin versus placebo, Outcome 4: Preterm delivery of a live infant

HISTORY

Protocol first published: Issue 11, 2017

Review first published: Issue 5, 2020

CONTRIBUTIONS OF AUTHORS

Eva N Hamulyák: prepared the current review; performed independent data extraction and quality assessment of the included trials, and commented on all drafts of the review.

Luuk JJ Scheres: prepared the current review; performed independent data extraction and quality assessment of included trials; commented on the drafts for this review.

Mauritia C Marijnen: prepared the current review; performed independent data extraction and quality assessment of included trials.

Mariette Goddijn: commented on all drafts of the review

Saskia Middeldorp: is the guarantor of the review; third reviewer for quality assessment; commented on all drafts of the review.

DECLARATIONS OF INTEREST

Eva N Hamulyák: none known

Luuk JJ Scheres: is a PhD-candidate of the CREW project (2013T083) funded by the Netherlands Heart Foundation

Mauritia C Marijnen: none known

Mariette Goddijn: has received travel expenses from European Society of Human Reproduction and Embryology regarding Executive Committee work (Amsterdam-Brussels) until July 2019. She works at both locations of the Department of Reproductive Medicine of the Amsterdam UMC (Location AMC and location VUMC). Location VUMC has received several research and educational grants from Guerbet, Merck and Ferring, outside the scope of the submitted work.

Saskia Middeldorp has received a Netherlands Organisation for Scientific Research (NWO) personal Innovation VIDI grant (paid to her institution) on Thrombophilia and Reproduction from the Netherlands Organisation for Scientific Research (NWO). She has carried out paid consultancy (paid to her institution, and not in relation to this review) for Daiichi Sankyo (as a member of the Writing Committee of the Hokusai VTE study (published in 2013)); Daiichi Sankyo, Bayer, and Janssen (local investigator for various treatment and prophylaxis studies in VTE patients). She has received payment (to her institution) for lectures on VTE treatment from Bayer, BMS/Pfizer, Boehringer Ingelheim, Daiichi Sankyo, Sanofi, and for developing educational presentations for Bayer, Aspen, Daiichi Sankyo, BMS/Pfizer). Saskia also has grants/grants for investigator-initiated studies from Aspen, Daiichi Sankyo and Bayer, all paid to her institution.

Saskia Middeldorp is supported by a VIDI grant from The Netherlands Organisation for Health Research and Development (016.126.364)

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

Pregnancy loss (total, early loss < 24 weeks, late loss ≥ 24 weeks) was stated as the primary outcome in the protocol. All trials reported live birth rates and most pregnancy loss as well, with only one trial reporting early or late pregnancy loss separately. Since pregnancy loss and live birth rate in fact describe the same outcome, we decided to redefine our primary outcome to live birth. Live birth and pregnancy loss are highly interrelated and in fact describe the (inverse of the) same outcome and the effects of the evaluated interventions. However, the size of the effect estimate will differ as it is an effect estimate of a relatively frequent event, i.e. live birth, as opposed to a less frequent event, i.e. pregnancy loss. Live birth is a patient-relevant outcome and the included studies all focus on live birth rate as well. We decided to redefine our primary outcome to live birth, as this also allows for a comparison with other studies in the area of recurrent miscarriage that have “ongoing pregnancy” (for instance after 12 or 20 weeks) as a primary outcome. Pregnancy loss is reported as a secondary outcome as well in a separate analysis for each comparison, in line with a recent Cochrane Review on progesterone for prevention of recurrent miscarriage (Haas 2019).

Our protocol stated two main comparisons; 1) heparin or aspirin, or both versus no treatment or placebo and 2) heparin with or without aspirin versus aspirin. We aimed to compare aspirin, heparin (either UFH or LMWH), a combination of heparin and aspirin with another or no treatment or both, as described in our protocol in the 'Types of interventions' section. For main comparison 2, heparin with or without aspirin versus aspirin alone, we did an additional subgroup analysis per type of heparin, as we feel that the outcomes per type of heparin are more relevant for clinical practice than the overall outcome for all heparins combined. Over the course of almost 25 years, clinical practice with regard to heparin treatment has changed from using UFH subcutaneously to the current standard of care of LMWH. For this reason, we consider reporting the subgroup results for both UFH and LMWH to be a more granular description of the evidence and highly relevant for current clinical practice.

We decided to split up main comparison 2, leading to two main comparisons and five comparisons overall in the current review 1) heparin or aspirin, or both versus no treatment or placebo, 2) heparin (LMWH or UFH) plus aspirin versus aspirin, 3) heparin versus aspirin, 4) LMWH plus aspirin versus UFH plus aspirin and 5) higher dose of heparin (LMWH or UFH) plus aspirin versus lower dose of heparin (LMWH or UFH) plus aspirin. We have GRADED all pre-specified outcomes and produced a Summary of findings table for main comparison 1 and 2.

In addition, according to our protocol, participants would be pregnant women with recurrent (two or more, which do not have to be consecutive) pregnancy losses in presence of persistent (on two separate occasions, at least 12 weeks apart) aPL. As the criteria for APS and testing for aPL changed (Miyakis 2006), studies prior to 2006 also evaluated women with persistent aPL, tested six to eight weeks apart. We decided to include all studies in which women had persistent antibodies; i.e. persistent presence of aPL, tested on two separate occasions, independent of the time-frame.
